Changes in Nervous System in Yellow Fever.—In a study of pieces of cerebral tissue from fourteen persons who died of yellow fever, Stevenson observed marked perivascular hemorrhage in various parts of the brain. He studied the whole brain in twenty cases of yellow fever. The chief lesion found in all the brains was perivascular hemorrhage. These hemorrhages were most frequent in the subthalamic and periventricular region at the level of the mamillary bodies. The temporal pole was the next most frequently involved area and the cerebellum only slightly less so. Perivascular lymphocytic exudate was present in nine cases and with the exception of a single case this was slight. Changes in the nerve cells were insignificant and no inclusion bodies were seen. Reactive changes in the microglia and astrocytes were slight. It is concluded that there is no definite evidence of neurotropism on the part of the virus of yellow fever.

Present Status of Serum Therapy in Pneumonia. R. L. Cecil, New York.—p. 104.
*Treatment of Pneumonia with Antipneumococcus Rabbit Serum. C. M. MacLeod, New York.—p. 116.

Antipneumococcus Rabbit Serum for Pneumonia.—The intravenous injection of a small amount of rabbit serum in the treatment of pneumonia, MacLeod states, is not to be recommended without first knowing the results of intradermal and intraconjunctival tests, since anaphylactic shock may occasionally occur in extremely hypersensitive individuals following the intravenous injection of as little as 0.1 cc. of well diluted serum. As a further precaution after the results of the tests are known, it has been the author's practice slowly to inject intravenously 0.1 cc. of the therapeutic serum diluted in 5 cc. of physiologic solution of sodium chloride. If a fall in blood pressure and an elevation of the pulse rate do not occur, it is considered safe to proceed with the therapeutic dose of serum. The reactions which may occur correspond to those following the use of horse serum. A total of 100 patients with conditions including infections due to pneumococci of nine different types have been treated. Eleven patients have died. Of the eleven who died, seven suffered from type III pneumonia. The final judgment on the efficacy of type III antipneumococcus rabbit serum has not been made, but in a certain group of patients a beneficial effect has occurred, particularly in persons before the sixth decade. In such patients a dramatic response may occur, similar to that which is seen so frequently in the serum treatment of type I pneumonia. Of the patients with type III pneumonia who died, only three could be considered as having received an adequate dosage of serum; but the fact that these patients died despite intensive treatment makes it imperative to pursue further the investigation of the therapy of type III infections. If the twenty-six cases of type III pneumonia are excluded from the series, the mortality rate is only 5.4 per cent. The patients who died, other than those in the type III group, illustrate the advantage of early treatment with antipneumococcus serum. All but one of these patients were treated late in the disease; in two, empyema was present associated with severe bacteremia; one patient had meningitis at the time of admission, and the fourth patient was an elderly man with type II pneumonia, who had consolidation of four pulmonary lobes when admitted to the hospital. Defervescence in twenty-five cases of type I pneumonia, treated with concentrated horse serum by the divided dose method, occurred in an average of 22.6 hours from the beginning of treatment. In twenty-six cases treated with unconcentrated rabbit serum, defervescence occurred in an average of 13.8 hours. However, in sixteen of these twenty-six cases the full therapeutic amount of serum was administered in less than two hours, and in this group defervescence occurred on the average in 9.3 hours. The same method of intensive therapy has been applied to the treatment of forty-eight cases of pneumonia due to other types as well. In many instances the full therapeutic dose of serum was given at one injection shortly after the patient was admitted to the hospital. In the remainder, treatment was completed within eight hours. The average time required for defervescence was only 9.75 hours. In practically all these cases the intradermal test with the specific polysaccharide was employed to determine when sufficient serum had been given. The author thinks that in the adult patient with uncomplicated type I pneumonia of not more than three days' duration a dose of 125,000 units should be given as soon as possible. After the third day a somewhat larger initial dose should be given, particularly if the consolidation involves more than one pulmonary lobe or if complications such as bacteremia are known to be present.

Anemia in Women with Low Incomes.—Kennedy states that 1,451 parous women of the child-bearing age, representing the poorer classes of the Montreal population, have been examined at the Child Welfare Association with special reference to the incidence of anemia. On no occasion did any of these volunteer women present themselves because of any symptoms of ill health. They were members of families in which the wage earners were unemployed or the monthly incomes were less than $100. Of the 1,451 cases 824 showed normal hemoglobin levels and 627 various degrees of anemia with hemoglobin levels less than 80 per cent. There were 377 persons with hemoglobin levels of 74 per cent or less. Moderate anemia (hemoglobin from 60 to 69 per cent) was present in 124 cases and severe anemia (less than 60 per cent) in sixty-four cases. The anemia was of the hypochromic type in all instances excepting twenty-one, in which the anemia was of the hyperchromic form. One hundred and nineteen women were seen during early pregnancy and sixty-seven of these had hemoglobin levels of less than 75 per cent. However, the majority of these women were retested one year after the termination of the pregnancy and the same degree of anemia existed. The study of 1,000 records in this series showed there was no conclusive evidence of any definite correlation between the presence of anemia and the number of pregnancies. There was also an absence of any significant correlation between the incidence of anemia and the history of hemorrhage, profuse menstruation or the interval between pregnancies. The approximate protein diet in fifty cases in which hemoglobin levels were between 75 and 100 per cent was compared with fifty cases in which hemoglobin levels were between 25 and 65 per cent. It was found that less protein in the form of beef, pork, liver, chicken and eggs was consumed by the anemic women. Approximately the same amounts of fish and milk were used by the two groups. Under ideal circumstances women require for health up to the age of the menopause about four times as much iron as men. Routine hemoglobin estimation in private and group health examinations will reveal many instances of adults supposedly in good health but actually suffering from varying degrees of idiopathic hypochromic anemia.

Rheumatic Infection in Childhood.—Bacal and Struthers compared the effect of surgical operations to eradicate foci of infection on the blood sedimentation rate of children suffering from rheumatic fever and normal children presenting themselves to the outpatient department for tonsillectomy. In none of the control children was a history of rheumatic fever elicited; likewise none of them gave a family history of rheumatic infection. The sedimentation rates were made immediately before operation, two days after operation, at the end of one week and at the end of two weeks. There were apparently three types of response in the normal children: 1. Some showed no alteration in sedimentation rate or loss of weight after operation. 2. Some showed a sharp rise and sudden fall of the sedimentation rate after operation, with an average loss of 2 pounds (1 Kg.). 3. The sedimentation rate fell to normal within the week following operation in a few children in whom it was elevated before tonsillectomy and continued at a normal rate for the period of observation. The children suffering from rheumatic fever or its manifestations showed reactions comparable on the whole to those of normal children. 1. The sedimentation rates were not affected by operation in some children with acute rheumatic fever who had no evidence of activity as shown by a normal sedimentation rate. 2. Some children who had no evidence of activity as shown by the sedimentation rate showed a sharp rise after operation. This rise in the sedimentation rate apparently may follow any surgical procedure, tonsillectomy, removal of carious teeth or surgical drainage of the paranasal sinuses. 3. In some children in whom the elevated sedimentation rate was the only evidence of activity, the authors concluded after prolonged observation that the elevated rate was probably due to foci of infection rather than to rheumatic fever. These children showed a sudden and sharp drop to normal and the sedimentation rate remained within normal levels during the period of observation. Weight loss in rheumatic children following surgical intervention is greater than in normal children. The surgical removal of foci of infection in a child with rheumatic disease is a definitely more serious undertaking than in the nonrheumatic child.

The Blood and Endocrine Disorders in Women.—During the last several years approximately 450 anemic women have been observed. An analysis of this group by Sharp and Mack revealed that 110 patients, or 25 per cent, had concomitant anemia and endocrine disorders. Complete diagnostic and therapeutic observations were obtained from sixty-eight of these women. A similarity in the symptomatology of the entire group of 110 patients permits classification into three groups: (1) from the menarche to 24 years, primary pituitary-thyroid deficiency, (2) from 25 to 39 years, secondary thyro-ovarian failure,

and (3) from 40 years to the menopause, premenopausal stage. Twenty-four patients were between the ages of 13 and 24 years. Six of the twenty-four had moderate erythrocytopenia on admission, while the remaining eighteen had severe anemia. Purpura was elicited in about half of this group. In the other two groups the average erythrocyte and hemoglobin levels were appreciably lower on admission than were the average levels for group 1. Group 2 resembled group one in that the predominant blood pattern in both was normochromic and normocytic in contrast to the predominance of microcytosis and hypochromemia in the older patients in group 3. Collectively, the average blood and hemoglobin levels showed a greater depletion in the two older groups. The authors believe that there is a definite anemia-endocrine syndrome in women. Definite signs of hypothyroidism, pituitary failure and hypogonadism are common to the syndrome. The anemia is usually normocytic in the adolescent and early adult age groups. Microcytosis and hypochromia appear to be expressions of chronicity of the anemic state, since they occur with greater frequency in middle-aged patients. Achlorhydria was frequent in all three groups, as were low basal metabolic rates, purpura, uterine bleeding, gastrointestinal disturbances and psychoneuroses. The authors believe that simultaneous treatment of the hematopoietic and endocrine disturbances by appropriate medicaments insures a favorable prognosis in a majority of cases. Gonadotropic substance in doses of from 200 to 1,000 rat units should be given daily until the uterine bleeding of immaturity is controlled. Thyroid extract to tolerance when indicated and iron salts are essential elements of the therapeutic plan for all three groups, when signs and symptoms indicate an appreciable degree of thyroid deficiency and mineral imbalance. The bleeding of maturity as well as the amenorrheic state encountered at any age is an indication for theelin in conjunction with gonadotropic substance. Curettement may be indicated at the outset and particularly when endometrial polyposis is present. Bed rest is desirable for patients having the severe periodic or continuous types of bleeding, but the majority of patients can be treated successfully without bed rest.

Build, Menstrual Disorders and Obesity.—In searching for the relationships between configuration and disease Bayer has made, since 1930, anthropometric and clinical studies of 110 women and girls whose complaints were thought possibly to be associated with their build. Those with obesity or menstrual disorders or both have been omitted and ninety cases are finally considered. The dominating symptom was menstrual disorder in forty-six, obesity in thirty-six, thyroid disorder in six and ectodermal dystrophy in two. In an attempt to sort patients into groups according to build, various measurements, indexes and dividing limits were tried until criteria were set up in which the photographs, the anthropometric measurements and the clinical diagnoses were in reasonable agreement. Eventually four groups were defined: feminine, hypofeminine, hyperfeminine and virile. The clinical testimony tends to corroborate the classification both in its lines of demarcation and in its developmental thesis. It has been possible to define each group not only as to build but also as to typical anatomic and physiologic corollaries. 1. In the normal feminine women the build is distinguished by normal body hair and breast development and average proportions, especially with regard to sitting height-stature and trunk-breadth indexes. Clinically these patients are usually normal except that there may be menstrual disturbances of flow and rhythm. 2. The build of the hypofeminine women is distinguished by scanty body hair, small breasts, long legs and a narrow pelvis. Underweight, primary amenorrhea, incomplete genital development, delayed bone age and increased sugar tolerance constitute the associated syndrome. 3. The hyperfeminine subject is distinguished by increased body hair, large breasts, short legs and a broad pelvis. Overweight, advanced bone age and decreased sugar tolerance constitute the clinical syndrome. Menstrual disturbances consist in irregularities of rhythm and flow. 4. The build of the virile type of woman presents excessive body hair, small breasts, short legs, broad shoulders and a narrow pelvis. Overweight, muscularity, secondary amenorrhea and masculinization of the genitals constitute the extreme clinical syndrome.

Preliminary Report on an Operation for the Cure of Meralgia Paraesthetica. F. C. Lee, Baltimore.—p. 147.

Ether Narcosis as Protection from Anaphylactic Shock.—Koontz and Shackelford gave shock-provoking doses of foreign protein to sixty-nine unanesthetized guinea pigs sensitive to it. Thirty-six of them lived and thirty-three died. Sixty-five guinea pigs sensitive to foreign protein were given shock-provoking doses while under ether anesthesia; fifty of these lived and fifteen died. Of the fifteen that died, one had pneumonia when it received the injections and another a completely atelectatic lung, shown at necropsy. A third died because the anesthesia was forced too far. A fourth death was probably due to the anesthesia. Two animals had pneumonia and atelectasis, *respectively, when the protein was injected; these conditions* were undoubtedly important contributing factors in their deaths. If these two animals and the one in which the anesthetic definitely caused the death are eliminated, there would be only twelve guinea pigs that died when injected during anesthesia. This would reduce the deaths to 18.5 per cent under anesthesia, as opposed to 47.8 per cent without anesthesia. In none of the animals dying without anesthesia was any underlying pathologic condition of the lungs revealed at necropsy: All of the unanesthetized group that survived showed marked symptoms of anaphylaxis. This was not the case in any of the anesthetized group. Of course, the anesthetic may have masked some of the clinical signs of anaphylaxis. The authors believe that there is a mechanical factor which produces effects entirely aside from the effects of the injected serum. If they are correct, they think that the percentage of deaths in the animals injected while under anesthesia would be further reduced. If these results are to be applied to man, the percentage of deaths is too high to indicate that it is safe to inject foreign serums into human beings under the assumption that anesthesia will afford complete protection against anaphylaxis. However, guinea pigs are more susceptible to anaphylactic shock; hence it is possible that any relative protection afforded by anesthesia may be more effective in man.

Sulfur Dioxide Poisoning as a Cause of Asthma. A. Romanoff, New York.—p. 166.

Roentgen Treatment of Asthma.—Maytum and Leddy used roentgen rays in the treatment of 215 cases of asthma. *These patients represent about 6 per cent of the total with* asthma who were treated at the clinic during 1935 and 1936. Twenty of the 215 cases are not included in the present report because treatment was incomplete or the diagnosis of asthma was questionable and another thirty-four cases are not reported because the patients were not followed closely enough. Of the remaining 161 patients, thirty-eight obtained more than 75 per cent relief, which lasted from one month to many months. *Twenty-three patients obtained as much relief but are not*

included, since other treatment given at about the same time may have been a factor in relieving the symptoms. Twenty-six patients had from 50 to 75 per cent relief for periods of one month or longer. The remaining seventy-four patients experienced less than 50 per cent relief, or more than 50 per cent relief for only short periods of time, and the results are accordingly classed as failures. Two of the patients in this group were completely relieved of asthma but died within a month, one from coronary occlusion and the other from postoperative infection. Five patients felt that their asthma was definitely worse after treatment. Even though at present the authors favor treatment through paravertebral fields, they do not advocate this method to the exclusion of all others. The beneficial effects from roentgen therapy are only temporary, and cures of asthma are not to be expected. They believe that the results obtained justify its use in cases of severe asthma in which relief has not been obtained with other measures.

Report of the Use of Biophotometer and Vitamin A Therapy in Industry. O. H. Schettler, R. F. Bisbee and B. H. Goodenough, East Pittsburgh, Pa.—p. 53.

Systemic Effects of Exposure to Chlorinated Hydrocarbons.—Chlorinated naphthalenes and diphenyls are used extensively for insulating wire and in the manufacture of electrical condensers. Because of the obvious need for more clinical data with regard to the effects of exposure to chlorinated naphthalene, Greenburg and his associates report three cases in persons who, after exposure in the course of their work to these known hepatoxic substances, died of acute yellow atrophy of the liver and in whose cases no other etiologic factors could be discovered after careful postmortem and clinical study. The plant conditions under which the patients had worked were carefully investigated. Two of the patients had suffered from at least one previous attack of hepatitis followed by a certain degree of improvement before the onset of the fatal attack. A papulopustular eruption was present in two cases. In one it antedated the systemic symptoms. This type of eruption is characteristic of the dermatitis caused by chlorinated naphthalenes and until recently was the only disturbance attributed to them. In the first case the cutaneous eruption apparently antedated all evidences of systemic disease. Had the girl been promptly removed from further exposure it is possible that her life would have been saved; or had the physicians first called on to treat the jaundice (of whatever origin) in her case or in the second case recognized the danger of continued exposure to the chlorinated naphthalenes these deaths might possibly have been averted. In order to prevent the condition the authors recommend that physicians should report all illnesses occurring among workers exposed to the chlorinated naphthalenes and diphenyls. Persons suffering from the typical acneform eruptions should be removed from further exposure. Employees who have had any liver disease—even a mild catarrhal jaundice—should not work with these substances; neither should those with a history of typhoid, malaria, gallstones or other diseases known to affect the liver adversely. Individuals receiving arsphenamine treatment for syphilis or those susceptible persons who are taking drugs believed to be injurious to the liver should not be further exposed to potential hepatic poisons. Persons working with the chlorinated naphthalenes and diphenyls, if requiring a general anesthetic for an operation, should not be given chloroform or tribromethanol in amylene hydrate and, vice versa, individuals who have recently received such anesthetics should not go back to their former work or to work with other substances believed to be potentially toxic to the liver. Pregnant women should not be exposed because the liver, in pregnancy, appears to be peculiarly susceptible to injury. With proper attention to ventilation and medical supervision of workers the chlorinated naphthalenes and diphenyls can be used in industry with safety.

Chemotherapy in Virus Diseases.—McKinley and his associates treated several experimental virus diseases (rabbit myxoma, rabbit fibroma, herpetic encephalitis, choriomeningitis and St. Louis encephalitis) with sulfanilamide, prontosil and sodium sulfanilyl sulfanilate. None of the compounds were of any therapeutic value in the diseases treated.

Lymphocytic Choriomeningitis.—Howard isolated a strain of the virus of benign lymphocytic choriomeningitis from the spinal fluid of a patient early in the course (sixth and seventh days) of the infection and when the cellular response in the spinal fluid was at its height. Abnormalities were slow in disappearing from the spinal fluid. Neutralizing antibodies in the patient's serum were demonstrated in low titer late in convalescence when mice as the test animals and the virus isolated from the patient were used. The patient's serum did not protect guinea pigs against Rivers' W. E. strain of the virus. Reinoculation experiments and the protection afforded by serum from Rivers' patient W. E. gave proof of the immunologic identity of this strain with others already described. The virus isolated lost its virulence for guinea pigs during constant passage through mice.

Neurogenic Tumors of Sympathetic System.—Wright and Paige report that three children who had neurogenic tumors of the sympathetic nervous system are alive with no evidence of recurrence or metastasis a year or more after the discovery of the tumors and their consequent removal. One patient is living

six years after removal of a sympathicoblastoma but retains her original signs and symptoms of compression of the spinal cord. One patient is well one year after the removal of a large pelvic ganglioneuroma. One patient is well one year after the discovery of a thoracic ganglioneuroma which has not been excised completely. Surgical removal of sympathicoblastomas followed by radiation therapy may occasionally be effective in preventing recurrence or metastasis.

Ascorbic Acid in Prophylaxis and Treatment of Scurvy.—Kenney and Rapoport gave nineteen infants crystalline vitamin C, 1.83 mg. per kilogram of weight daily, for five months as a prophylactic against scurvy. No clinical or x-ray evidence of scurvy was apparent during the period of observation. Crystalline vitamin C was used in the treatment of twenty-one cases of infantile scurvy and satisfactory healing was obtained. The presence and significance of fever in the scorbutic infant are analyzed, and the lack of temperature elevation following the administration of vitamin C is pointed out. There was no constant effect produced on the capillary resistance (capillary fragility test) in the scorbutic infants following the administration of vitamin C. Crystalline vitamin C seemed to stimulate wound healing in the incision of an infant operated on for pyloric stenosis in whom there was no evidence of healing prior to its administration. Intravenous administration of vitamin C seemed to have no effect on the hematuria in a case of subacute hemorrhagic nephritis.

Acromioclavicular Dislocation.—Anderson and Burgess state that acromioclavicular dislocations, easily and quickly reduced in most cases, prove exceedingly difficult if not impossible to hold reduced by the unsatisfactory dressings in current use. Regardless of the degree of dislocation, a reduction can usually be effected in fresh cases by elevating the shoulder upward and forcing the outer end of the clavicle downward, *thus opposing the joint surfaces. Uninterrupted maintenance* in this position for a period of several weeks will allow the ligaments to heal. The authors believe that a dependable and physiologic means whereby acromioclavicular dislocations may be reduced and held is provided by use of Anderson's suspension-hammock clavicle splint. To this splint one addition is made, a single strap over the injured shoulder. This strap attaches to the frame of the splint, front and back, and furnishes a means whereby the clavicle is firmly held down in normal position. With this method reduction cannot be lost, yet there is no undue compression on axillary or shoulder structures and the patient is permitted comparatively free use of the arm. The splint allows elevation of the shoulder by suspension along correct anatomic lines, since adjustable points of motion lie over both the sternoclavicular and shoulder joints. The hammock is molded to conform to the normal axilla and is constructed of resilient rubber, avoiding compression of the axilla. Since the weight of the shoulder is transmitted first to the sternoclavicular area and then to the base of the splint, there is no tendency for dragging or instability. The acromioclavicular strap which passes over the injured shoulder furnishes a means of counterpressure which is mechanically secure, since it is attached to the front and back of the same frame that supports the hammock. By this method patients are ambulatory and can wear their regular clothing. They are unusually comfortable with the splint in place. General anesthesia is unnecessary in reducing the dislocation and applying the splint; in fact, application is facilitated by having the patient sitting or standing. An injection of morphine will usually suffice. The splint is left continuously in place throughout healing. When only the capsular ligaments are torn and the conoid and trapezoid ligaments are intact, splinting for from two to three weeks is sufficient. In complete dislocations the fixation should remain in place for at least six weeks; frequently twelve weeks is necessary for complete healing. Care should be taken not to use the arm for lifting or any other heavy work. The strap across the injured shoulder should be kept tight. Regular x-ray inspection should be made to see that reduction is firmly maintained. Following removal of the splint, graduated active restoration of the function of the shoulder is carried out. The conservative method outlined will not be applicable in all cases. Old dislocations which have gone untreated and the occasional fresh one which is difficult to hold reduced because of the interposition of soft tissues in the joint will need an open reduction. Postoperative splint fixation for six weeks or more should be regularly carried out as supplementary support to internal fixation.

Gastrointestinal Symptoms in Anorectal Disease.—In discussing the digestive disturbances referred by anorectal disease Gauss cites in detail a case, among fourteen others, in which the digestive syndrome suggested peptic ulcer and irritable colon but examination revealed hemorrhoids, the removal of which was followed by rapid improvement. Apparently in this case the hemorrhoids were responsible for the digestive distress. The mechanism of the production of digestive symptoms of anorectal origin is generally considered as taking place through the sympathetic and parasympathetic nervous system. It is believed that a constant irritation at the anorectal region may give rise to the irritable colon syndrome and that this may be followed by the gastric irritation syndrome. There *are no digestive symptoms which are pathognomonic of ano*rectal origin. In thirteen cases the successful treatment of

the anorectal disease was followed by prompt relief of the digestive distress. The author did not encounter gallbladder, appendical or true peptic ulcer syndromes as reported by other investigators. Practically all his patients complained of the irritable colon syndrome. The symptoms complained of were chronic constipation, unsatisfactory infrequent stools, incomplete stools, tenesmus, cathartic or enema habits, occasional attacks of diarrhea, abdominal distress under the left and right hypochondria and in the left iliac region, flatulence and belching. In some cases the gastric irritation syndrome was present. Heartburn in the epigastrium and sometimes under the left costal margin, which occurred several hours after eating, was relieved by sodium bicarbonate. While the gastric distress in anorectal disease resembles the peptic ulcer syndrome, it can be easily differentiated from true peptic ulcer by the diffuse area it involves, by its lack of definite periodicity and by x-ray study which does not reveal organic changes in the stomach or duodenum. The gastrointestinal symptoms are purely functional in character and clear up when the offending lesion at the anorectal region is corrected.

Effect of Gastrectomy on Gastric Juice.—St. John and his colleagues analyzed the gastric secretion of twenty-six patients after partial gastrectomy for peptic ulcer. Eleven patients had originally suffered from gastric ulcer, thirteen from duodenal ulcer and two from combined ulcers. The interval which had elapsed between the operation and the time of examination varied from one month to nineteen years. Free hydrochloric acid was absent in twenty-two cases, diminished in three and within normal limits in one. Combined acidity exceeded 10 degrees in sixteen of the twenty-six cases and was as high as 24 degrees in a case of achlorhydria. The *pH* of the gastric contents not containing free hydrochloric acid varied between 4.2 and 6.4 and was in the neighborhood of 5 in the majority of instances. The *pH* of the specimens containing free acid was approximately from 1.2 to 1.4. No explanation could be found for the failure of anacidity to develop in four of the cases. Achlorhydria was usually manifested in patients recently operated on and in those operated on from five to fifteen years previously. There was no tendency for free acidity to persist in patients who had originally suffered from ulcer of the duodenum. Two of the four patients whose gastric secretion still contained free hydrochloric acid had extensive gastric resections. It was impossible to determine in retrospect the amount of stomach which had been removed in many instances. The impression was gained, however, that the antral portion of the stomach had not been completely removed in some of the patients with anacidity. Determinations of pepsin were carried out in twenty-four cases. The results show a marked diminution in the peptic activity of gastric juice after partial gastrectomy in almost all instances. In all but three cases the amount of pepsin was found to be below the range found in patients with peptic ulcer who were not operated on. In two instances no peptic activity was demonstrable. The specimens which contained free hydrochloric acid showed relatively large amounts of peptic activity. Twenty-two patients of the group, twelve of whom have been followed for more than three years, have been completely free of symptoms of ulcer during the entire follow-up period. The remaining four patients have suffered from recurrent abdominal pain or melena, attributed in each instance to jejunal ulcer. In one of these patients the presence of jejunal ulcer was proved at exploration. The gastric juice of this patient contained free hydrochloric acid. The other three patients who had had recurrent symptoms showed anacidity. The studies offer no explanation for therapeutic failure in these cases. In most instances, however, the occurrence of achlorhydria after partial gastrectomy for peptic ulcer offers a satisfactory explanation for the successful results.

Gynecomastia.—Wernicke reports four cases of gynecomastia with similar characteristics. All but case 4 were unilateral. All gave a history of trauma. All occurred while the patients were in their teens. Not one of them showed any glandular evidence of disturbance except of the testicles and all but patient 2 had an atrophied left testicle. The Aschheim-Zondek test was negative in the three that were given treatment (testosterone propionate). The other, patient 3, was not examined as he did not return. Libido was increased in two of the three cases treated and was very much present in case 3. If case 2 were merely one of testicular hypofunction, for the testicles were equal in size, it might have been expected that testosterone would stimulate them enough to cause at least some change in the breast; but it had no apparent effect. Nor has anterior pituitary substance had any effect in this patient after two months of treatment. Favorable results were obtained in cases 1 and 4, as opposed to the unfavorable result in case 2, in spite of the fact that in all practically the same treatment was administered. This may be due to two factors. In cases 1 and 4 there was marked atrophy of the left testicle, while in case 2 the testicles were equal in size and apparently normal. In cases 1 and 4 the breast enlargement occurred earlier after puberty (at 16 and 14 years respectively) than in case 2, in which the breast enlarged when the patient was 19 years of age. Patient 4, whose breasts enlarged at 14 and whose treatment was given at 16, responded more quickly than patient 1, whose breast enlarged at 16 and received treatment at 20. Age, therefore, may be an important factor. The favorable outcome in two of the three cases of gynecomastia treated with testosterone propionate suggests that endocrine therapy should be given a thorough trial before surgical removal of the breast is advised. In case 1 enlargement of the breast recurred spontaneously, associated with recurring atrophy of the left testicle. The resumption of treatment with testosterone has produced no change in three weeks (after 165 mg. of the substance). This suggests that probably replacement therapy with testis hormone preparations at regular intervals will be found necessary to maintain a cure once it has been effected.

Arthrodesis in Tuberculosis of Hip Joints.—Pask states that over a period of four and a half years 131 patients (seventy-six adults and fifty-five children) have been admitted to Wrightington Hospital with tuberculosis of the hip. Arthrodesis was performed on eleven of these patients (nine adults and two children). It is the author's practice to operate only when the disease may be said to be reasonably quiescent. In very young children such an extensive operation is never justifiable. Arthrodesis of the hip is not a life-saving measure; its purpose is the conversion of a weak, yielding ankylosis into a sound, immobile, painless fixation which will not yield to weight bearing and will not alter its angle at a later date. The combined operation of intra-articular and extra-articular arthrodesis has been done whenever possible. The combined procedure has the advantage of removing all the diseased tissue at the time of the operation, and if for any reason the extra-articular fixation is unsuccessful there is a possibility of a firm ankylosis following the approximation of the denuded femur and acetabulum. The graft in every case was taken from the anterior part of the ilium. The lower part of the graft was not detached from the ilium before it was turned down; this is important, as the chances of the graft taking are considerably increased by adopting this method. In eight of the eleven patients operated on healing occurred by first intention, in three the wound broke down and of these one ultimately died with multiple sinuses. A firm bony ankylosis in good position was obtained in nine cases; in one case the ankylosis was not absolutely firm, but the patient was working and suffered no disability; the patient who died also showed a bony ankylosis in spite of severe suppuration. Five of the patients are working at their normal occupation, three are fit for work but are unemployed, one is doing domestic duties at home and only one is unfit for work.

Relation of Growing Pains to Rheumatism.—After a lapse of four years Hawksley reexamined sixty-four unselected cases from the 115 cases of growing pains seen in 1934. None showed any evidence of cardiac involvement. Adding these cases to Sheldon's, it is seen that of 253 children followed up for four years at the Hospital for Sick Children evidence of rheumatic heart disease developed in only two, or less than 0.8 per cent. The incidence of cardiac rheumatism in 301,392 school children examined in 1936 was 0.8 per cent. Growing pains and rheumatism resemble each other only to the extent that both produce pain in the limbs. A correct differential diagnosis is imperative, for, while rheumatic cases with potential carditis should be treated by rest, it is bad to make invalids out of children with growing pains by treating them for rheumatism. The following clinical features serve to distinguish the two conditions: 1. Rheumatism affects joints and is usually accompanied by tenderness on pressure and movement. There may be redness, swelling or effusion. In growing pains, muscles, ligaments and tendons are usually the site of the pain; tenderness is rare and there is no swelling, effusion or redness. The pain is more nagging and more likely to cause crying in the nonrheumatic case. 2. In growing pains a cause of the pain is often found in postural or orthopedic defect. Tiredness and vague ill health are common to the two diseases, but patients with growing pains are usually sulky and unsociable; this, in the author's experience, is uncommon in rheumatism. 3. Nodules do not occur except in rheumatism. 4. There is no significant change in the temperature in cases of growing pains. There is also no tachycardia. 5. Cases of growing pains as a rule show no anemia; rheumatic cases frequently do. 6. In cases of growing pains there is no antecedent sore throat. 7. There is no lengthening of the PR interval on electrocardiography in cases of growing pains.

Erythema Nodosum and Tuberculous Lymphadenitis.—Thompson describes six cases of erythema nodosum associated with acute tuberculosis of the cervical lymph nodes. The tuberculous infection is believed to be recent and to have gained entrance by way of the tonsil in three, septic follicular tonsillitis having been a contributory cause of this port of entry and possibly also of the subsequent softening and suppuration of the tuberculous lymphadenitis. In the other three cases, tuberculosis was known to have been present for a number of years. The exacerbation in the cervical lymph nodes concurrent with the onset of erythema nodosum is attributed to reactivation of tubercle bacilli latent in the lymph nodes in two cases and in the pulmonary parenchyma in the third case. However, the possibility of exogenous superinfection must be admitted. The pathogenesis of the cutaneous lesions is discussed and their identity as hematogenous tuberculous foci is suggested by the concomitant phlyctenular keratoconjunctivitis in two cases. These lesions underwent exacerbation and remission more or less coincidentally. This occurrence suggests that erythema nodosum may signalize the development of resistance by the host in addition to cutaneous hypersensitiveness, or in other words the accompaniment of allergy by immunity. The paradox of an effect at once beneficial to the lymphadenitis and deleterious to the phlyctenular disease accords with Rich's theory of immunity and allergy as separate, even antagonistic, entities, the latter causing caseation and destruction in defensive tubercles built up by the former.

Cause of the Difficulty of Treating Amebiasis.—It is generally known that acid reaction of stools favors the life and growth of Endamoeba histolytica. On this hypothesis Ghosh treated three patients with chronic amebiasis, whose stools were highly acid to litmus, with one course of six injections of 1 grain (0.065 Gm.) of emetine followed by the oral administration of freshly prepared liquid extract of kurchi for twelve consecutive days while the patients were kept mainly on a protein diet with a restricted amount of carbohydrate. The stool turned alkaline after forty-eight hours. The restricted diet was enforced in each

instance for four weeks and the patient was advised to test the reaction of the stool daily with litmus paper. The restriction of diet was lifted after four weeks but the patients were instructed to avoid rice and sweets as much as possible. During the period of observation several examinations of the stools of each were made; up to the time of writing all three patients were free from amebas. The patients had been following instructions regarding diet, though they said that it was hard to avoid rice and sweets. The general health of these patients has greatly improved. The author draws no conclusion but does suggest that in treating cases of chronic amebiasis strict attention should be paid to the adjustment of the diet in such a way as to keep the reaction of the stool alkaline. Alkali by mouth can change the reaction of the urine but has little influence on the reaction of stools. A change to atta from rice changes the reaction of the stool from acid to alkaline.

Placental Blood for Transfusion.—The average quantity of placental blood that Howkins and Brewer collected from fifty consecutive women at term is small, 47 cc., which compares unfavorably with Goodall's and Grodberg's figures of 125 and 105 cc. respectively. This small yield would necessitate the mixture of from ten to twelve samples to supply the bulk of blood usually employed in an adult transfusion and it is questionable whether this extensive pooling of several bloods, although of the same group, is entirely devoid of the risk of the minor subgroup reactions of agglutination. With regard to sterility, 22 per cent of the samples were contaminated with airborne or genital tract organisms (Bacillus subtilis, Bacillus coli, Bacillus pyocyaneus and Streptococcus albus) after a reasonably aseptic technic. The authors can agree neither with Goodall in his assertion that culture of the collected blood is unnecessary nor with Grodberg in his statement that any stray organisms present are usually killed by the leukocytes—a statement which they have proved to be incorrect, in that their second culture always tallied with the first, and organisms if present on the seventh day of storage always survived up to the time of subsequent culture. This source of blood for transfusion, however carefully perfected the technic of its collection, sterilization and storage may become, is unlikely to rival seriously that available through the voluntary donor system.

Prophylaxis of Tuberculous Empyema.—The incidence of tuberculous empyema in patients with artificial pneumothorax is about 10 per cent and its fatality rate, in published reports, about 50 per cent. Therefore it seems to Roberts that prevention seems especially important. He suggests that persistent or recurrent pleural pain over the lesion indicates severe tuberculosis of the pleura, which contraindicates artificial pneumothorax. The risk of empyema is sufficiently great to make some other form of collapse therapy advisable. The object of artificial pneumothorax is relaxation, not compression, of the lung. High positive pressures to "stretch the adhesions" are not justifiable. After adhesions have been cauterized and collapse has been instituted, a pneumothorax which remains ineffective should be promptly abandoned and other collapse therapy substituted. Oleothorax and extrapleural pneumothorax are valuable in certain cases.

Renal Changes in Malignant Hypertension.—Wilson and Byrom present evidence that chronic interstitial nephritis may be caused by hypertension alone. Compression of one renal artery of 157 rats gave rise to hypertension in 101 (65 per cent). The blood pressure may be elevated as early as eighteen hours after the first operation or may begin to rise at any time during the first four weeks. The course of the hypertension varies considerably, but in general two types were recognized: 1. That in which the blood pressure rises gradually over a period of several weeks to reach a steady high level, which has been maintained for nine months in animals still under observation and appears to be consistent with normal health. 2. That in which the hypertension runs a more irregular course and often leads to a state of great weakness, wasting, coma and occasionally convulsions. The close resemblance between the renal lesions produced in the rat by experimental hypertension and those found in cases of malignant hypertension in man bespeaks a common pathogenesis. It provides experimental support for the clinical evidence that malignant hypertension is a form of essential hypertension of which renal disease is but a terminal manifestation. Since a similar picture occurs in the hypertensive rat under conditions which apparently exclude the influence of "toxic" agents, the authors infer that inflammatory changes can result from a hypertension severe enough to produce arterial necrosis. The demonstration that arterial lesions can be produced in the kidney by experimental hypertension also throws light on the clinically malignant course of the human disease; for when vascular lesions occur in malignant hypertension as a result of the high blood pressure they will presumably give rise to a reduction in renal blood flow. This may be expected to aggravate the hypertension, and so a vicious circle will be established in which a rising blood pressure is associated with progressive renal destruction. It appears that not only "essential" hypertension but also hypertension secondary to renal disease can set in motion the vicious circle. This "malignant termination" has therefore no specific character derived from the original disease but is an attribute of the high blood pressure which is common to all. The clinical symptoms in the hypertensive rat are closely related to the human disease. In animals moribund from this condition immediate and lasting improvement, with return of the blood pressure to normal, has been produced by excision of the ischemic kidney. The syndrome appears to be a close counterpart to hypertensive encephalopathy in man (the pseudo-uremia of Volhard).

Miners' Dyspnea.—The Petersons and Startup examined thirty-six coal miners whose respiratory disability (dyspnea) was such that they have had to give up their occupation. From this they conclude that the vital capacity per unit of body surface gives, in these instances, a more reliable estimate of the degree of respiratory incapacity than do the roentgenograms.

*Investigations on Hypoglycemia. F. Turyn.—p. 41.
Latent Chronic Pancreatitis. J.-V. Grott.—p. 57.

Investigations on Hypoglycemia.—Turyn says that, since the introduction of insulin in the therapy of diabetes mellitus, hypoglycemia has become more and more frequent and now the symptoms of hypoglycemia are well known. In severe cases they are general weakness, asthenia, abulia, sweats, hunger, tremor, shock, headache, vertigo, diplopia, convulsions, delirium and hypoglycemic coma. In the mild cases the symptoms recall excitation of the sympathetic. There are many theories about the pathogenesis of the symptoms of hypoglycemia but the majority of authors explain their appearance by epinephrine counterregulation. The author says that signs of hypoglycemia concur with widely differing blood sugar levels. Nevertheless, in the majority of cases subjective signs appear with values of from 80 to 70 mg. per hundred cubic centimeters and objective symptoms are generally noticeable with values of from 70 to 50 mg. per hundred cubic centimeters. The simultaneous determination of the sugar content of the venous and of the capillary blood gives variable results. In this report the author is concerned chiefly with this difference in the capillary and venous glycemia and with its relation to the signs of hypoglycemia. He made a series of investigations to determine whether the diverse signs of hypoglycemia are connected with the augmentation or diminution of the difference between capillary and venous glycemia. He determined the sugar content, according to the method of Hagedorn and Jensen, of blood specimens that were obtained from the finger and from the ulnar vein of the same member. From 20 to 30 units of insulin was injected while the persons were still fasting and then observations were made on the pulse rate and the arterial tension; moreover, the persons were carefully watched for signs such as flushing, pallor, dryness of the mouth, generalized tremor and hunger. Studies were made in sixteen cases. On the basis of these observations the author arrived at the conclusion that the symptoms of hypoglycemia appear in relation to the variations of assimilation of sugar in the peripheral tissues, that is to say with the augmentation or the diminution of the difference of the capillary-venous glycemia. The augmentation of this difference manifests itself as a hypoglycemia of great intensity, in which the symptoms of excitation of the vagus nerve dominate. This is then an insulin intoxication. The diminution of the aforementioned difference is accompanied by the symptoms of epinephrine shock. The absence of signs of hypoglycemia, in spite of a low glycemia, can be explained by the absence of variations of assimilation of sugar in the periphery. Epinephrine shock appears when the hyperepinephrinemia succeeds in mobilizing the glycogen of the liver.

*Roentgen Therapy of Furuncles. G. Ronneaux, H. Desgrez and F. Degand.—p. 17.
Tubes for Roentgen Therapy with High Intensity: New Model; Exterior Anticathode. J. Belot.—p. 19.

Roentgen Therapy of Furuncles.—Ronneaux and his associates point out that roentgen therapy of furuncles produces such favorable results that this treatment is being rapidly adopted in France. In this paper they report observations on twenty-six patients who had either grave furuncles (of the face) or carbuncles. A table listing the twenty-six cases indicates the localization of the furuncles or carbuncles, the type of irradiation, the number of treatments, the number of roentgens administered at each session, the total dose and the outcome of the treatment. The first five patients were irradiated with soft rays, the tension being 120 kilovolts and the filter consisting of 1 mm. of aluminum. Another group of six patients was treated with harder rays; the tension was 150 kilovolts and the filter consisted of 0.2 mm. of copper and 2 mm. of aluminum. In the last group of patients the authors employed 180 kilovolts filtered through 0.5 mm. of copper and 2 mm. of aluminum. They gained the impression that the harder type of rays effected a more rapid improvement. In the majority of cases, 50 roentgens each was given in the first two sessions and 100 roentgens in a third session. The treatments were given every other day, so that five days was required. To be sure, in some of the cases the total dosage was greater and a longer period was required. The majority of the patients had furuncles of the face, and the authors observed no grave complications in the course of the evolution. Some had generalized furunculosis. It is difficult to render an opinion on the effect of irradiation of a furuncle on the evolution of furunculosis. The authors gained the impression that the treatment of a furuncle modified the evolution of furunculosis favorably, but they learned that several of the patients had relapses after temporary remissions.

After Twenty Years of Gastric Surgery for Ulcer of Stomach. J. Abadie.—p. 219.
*Tuberculosis and Anal Fistula. R. Kaufmann.—p. 221.

Tuberculosis and Anal Fistula.—Kaufmann says that anal fistulas are in many instances tuberculous. Observations in 101 cases led him to think that it is extremely difficult or even impossible to furnish the proof that a fistula is tuberculous. He shows that the frequency of tuberculous anal fistulas has been exaggerated, because numerous reports in France as well as elsewhere have been based on insufficient evidence. He thinks that some want to justify the belief in the habitual concurrence of tuberculosis and anal fistulas, because this conjecture has the advantage of excusing therapeutic failures. Discussing the histologic aspects and particularly the appearance of giant cells he says that, although it is well known that giant cells are not specific for tuberculosis, reports on tuberculous anal fistulas frequently have no other basis than the microscopic demonstration of giant cells. In the course of fifty-four operations for anal fistulas the author found giant cells in six patients. In three of these the local and general evolution indicated a tuberculous process. But the author does not believe that this was the case in the other three, for the latter patients did not have tuberculosis and they were completely cured. After reporting the clinical histories of these patients the author discusses anal fistulas in patients with pulmonary tuberculosis and relates the histories of fourteen. In the evaluation of his entire material of 101 cases, he first repeats that in the aforementioned fifty-four cases of anal fistulas he detected three that were of a tuberculous nature. In a group of thirty-two patients with anal fistulas he failed to detect a single tuberculous case. Thus in a total of eighty-six cases of anal fistula only three were found that were of a tuberculous nature. Even if the fifteen cases from a department for pulmonary tuberculosis are added, it can be said that in 101 operations for anal fistula the tuberculous nature of the fistula was detected ten times at the most. Returning to the difficulty that is involved in deciding whether an anal fistula is tuberculous or not, the author says that, if the presence of giant cells does not have absolute diagnostic value and if the aspect of the fistula, the presence of pulmonary tuberculosis or the weak condition of the patient are not sufficient proof, all the same the morbid entity of tuberculous fistula does exist and it is necessary to affirm it in the presence of the concordance of the three factors which, when isolated, are not convincing. These factors are poor aspects of the fistula, giant cells and pulmonary tuberculosis.

47: 241-256 (Feb. 15) 1939

*Late Results of Treatment of Bronchial Asthma by Stellectomy. R. Leriche and R. Fontaine.—p. 241.
*Treatment of Staphylococcic Infections by Crude and Purified Specific Anatoxin. A. Bocage, P. Mercier and R. Richou.—p. 243.

Stellectomy in Bronchial Asthma.—Leriche and Fontaine review the late results of stellectomy in bronchial asthma, pointing out that thus far they have employed this surgical therapy in fourteen cases of bronchial asthma. Two of the cases were lost sight of and so the authors were able to determine the late results in only twelve. After giving brief histories of

these cases, they summarize the results in a table. The fifth patient underwent three interventions: chondrectomy, which failed, stellectomy, which seemed to aggravate the condition, and vagotomy, which ameliorated the disorder for about a year, after which time the patient was lost sight of. This case is also excluded from the estimation of the late results and so only eleven cases remain, in all of which either unilateral (left side) or bilateral stellectomy was done. In six of these eleven cases, that is, in approximately 55 per cent, the results were favorable. Complete cessation of the asthmatic attacks was observed in two of these cases for periods of thirteen and seven and one half years respectively. In another case there was complete cessation of the attacks for seven years and then there was a partial relapse. In three other cases great improvements were observed, which still persisted after four, five and one half and two and one half years. In five cases, that is in about 45 per cent, the stellectomy failed to produce lasting improvement of the bronchial asthma. The authors think that, among the different surgical methods which have been recommended for bronchial asthma, stellectomy is the method of choice, because the technic is simple and outside of Bernard-Horner's syndrome it causes no neuroparalytic sequels. Infiltration of the stellate ganglion is regarded as a surgical adjuvant; it suppresses the severe asthmatic attacks and thus time is gained; moreover, to a certain extent it may be helpful in selecting the cases that will respond favorably to an operation. The authors conclude from their studies that, when all other treatments have failed, an operation on the sympathetic can be tried to improve the lamentable condition of patients with asthma.

Specific Anatoxin in Staphylococcic Infections.—Bocage and his associates point out that in 1929 Burnet obtained for the first time a true staphylococcic toxin. This prepared the way for the production of a staphylococcic anatoxin (toxoid) analogous to the diphtheric anatoxin (toxoid) of Ramon. The authors have treated staphylococcic infections with a specific toxoid since 1934. In an earlier report (*Presse méd.* **43**:1137 [July 17] 1935; abstr. THE JOURNAL, Sept. 28, 1935, p. 1080) they described the results which they obtained in approximately 100 cases. In the course of the ensuing years they followed as much as possible the fate of their first patients and treated hundreds of new ones and they always found the therapeutic activity of toxoid superior to all the other treatments. In the present report they examine the results that were obtained since June 1937. Following a discussion of toxicogenesis in staphylococci they give their attention to the clinical study of cutaneous staphylococcias. Regarding the mode of application of the toxoid, they say that it is necessary first to test the allergic susceptibility of the subject by subcutaneous injection of 0.1 cc. of the toxoid. If this first injection produces neither fever nor local reactions, treatment is continued with 0.25, 0.5, 1 and 2 cc. The injections are given hypodermically into the supraspinous fossa or into the flank at average intervals of four days. It should not be neglected to precede the treatment by an albumin test of the urine; if this test is positive, it is advisable to defer the toxoid treatment. In subjects who are sensitive to vaccines, the treatment should be begun with 0.05 cc. This dose should be repeated two or three times at two day intervals and, if reactions are absent, the treatment can be continued with the usual doses. In children the toxoid therapy should likewise be begun with 0.05 cc. and this dose should be followed by 0.1, 0.25 and 0.5 cc. The clinical results which the authors obtained with the toxoid are indicated in tables and several case histories are reported. In the conclusion they state that, on the basis of more than 2,000 observations, the efficacy of specific toxoid in the treatment of staphylococcic infections, particularly those of the cutaneous type, appears incontestable. They hope that in the near future they will be able to proceed with more success against the grave forms of staphylococcic infections, especially the septicemias and osteomyelitis. This will be possible when they have at their disposal a purified toxoid of an antigenic power that is still higher than is available at present. Numerous observations made by the authors and by other clinicians and experimental studies confirm their opinion that the antitoxin plays the essential part in the mechanism of antistaphylococcic immunity.

*Problem of Etiology of Infantile Acrodynia. R. Debré and A. Névot. —p. 253.
Induced Premature Birth and the Triad Grave Familial Icterus, Congenital Anemia and Universal Congenital Hydrops. Cornelia de Lange. —p. 277.
Vitamin C Metabolism of Healthy and Diseased Children. L. F. Meyer and P. Robinson.—p. 283.
Sulfur and Protein Metabolism of Breast Fed and Artificially Fed Nurslings. S. Blazsó.—p. 302.

Etiology of Infantile Acrodynia.—Debré and Névot call attention to the fact that one of them (Debré) suggested in 1927 that ergotism, ustilaginism, infantile acrodynia (pink disease or erythredema) and pellagra belong to the same nosologic group. Recent reports by Mayerhofer and Dragisic confirm this view. In ergotism and ustilaginism the toxic-alimentary origin has been definitely established and the authors think that the same etiologic factor plays a part in acrodynia and pellagra, although for the latter two disorders the exact cause of the alimentary intoxication has not been demonstrated as yet. In their experiments on animals (mice and monkeys) they show that symptoms similar to those of the aforementioned diseases (vasomotor, trophic and paralytic symptoms) or even death can be produced by feeding the animals with extracts of ergot, of Ustilago segetum, of brown rust of wheat (*Tilletia tritici*) or of the seeds of corncockles. The animal experiments demonstrated particularly the toxicity of brown rust of wheat, contained so frequently in human foods, but also of blight of wheat and of the seeds of corncockles, which are more rarely ingested. Numerous epidemiologic investigations undertaken by the authors in different parts of France failed to establish that in the regions where infantile acrodynia was prevalent the food taken by the children or the fodder of the cows contained the aforementioned toxic substances. Nevertheless the etiologic problem remains and in order to ascertain the etiology of acrodynia and to see whether the theory of a toxic-alimentary origin is right it is necessary to study carefully the dietary regimen of the little patient and the possible parasitic infestation of his food, including the milk, which may contain toxic substances of a vegetable origin.

Hemolytic Icterus (Hemolytic Constitution) and Gastric Changes. S. Brandli.—p. 149.
*Nontropical Sprue and Pregnancy. A. Spreng.—p. 150.

Erythroblastoses of the Newborn.—Albrecht says that the collective term of erythroblastosis of the newborn was applied at first to hydrops foetus universalis, icterus gravis familiaris and congenital anemia. Later the term erythroblastosis was extended to include several disorders of nurslings and young children such as Cooley's anemia, the erythremia of Italian authors and Jaksch-Hayem's anemia (anemia infantum pseudoleukemia). About the nature of the erythroblastoses, the opinions are divided. On the one hand they are regarded as a nonspecific reaction of the hemopoietic organs to a previous noxa, on the other hand as systemic diseases. The author shows that the various forms of erythroblastoses differ in severity but have several symptoms in common. The first of these is the erythroblastosis, to which is added a more or less severe flooding out of myeloid cells; the second symptom which they have in common is the swelling of liver and spleen and the third one is anemia. Another factor which indicates that the diseases belong together is their frequent familial concurrence; it has been observed that two or three forms occur in the same family. After reviewing the clinical aspects of hydrops foetus universalis, of icterus gravis and of congenital anemia, the author describes four cases that were observed at the children's clinic in Basel. In the summary he emphasizes that erythroblastosis cannot be regarded as a primary disease of the blood but as a reaction of the fetal hemopoietic organs to a previous noxa. The hematologic symptom is nearly

always present but often only for a brief time; however, it permits the early diagnosis and a suitable treatment. In the reported cases the treatment consisted of injections of a liver preparation and of parental blood and in some cases of blood transfusions.

Nontropical Sprue and Pregnancy.—Spreng says that a review of the recent literature on anemia in pregnancy discloses little about nontropical sprue in pregnant women. He gives a detailed report of a case observed at his hospital concerning a woman who had nontropical sprue, bronchiectasis and pulmonary tuberculosis. In the course of a triplet pregnancy the conditions became greatly exacerbated. The spontaneous, premature delivery of the triplets was followed by grave complications that threatened the life of the patient. The recovery was slow. The author cites another case of megalocytic anemia in a pregnant woman who was hospitalized only at the end of her pregnancy, when she was in a poor and cachectic condition. She died shortly after the delivery as the result of circulatory weakness. In both of these cases the pregnancy severely complicated the nontropical sprue, and the author concludes that it is advisable to interrupt the pregnancy in such cases. Regarding the therapy, he says that in the first case treatment with yeast was the only measure which was really effective. Cases of sprue which develop during pregnancy and perhaps as a result of it are unknown to the author. However, he thinks that the megalocytic anemias, which are so frequently observed in the tropics in pregnant women who have a B_2 insufficiency, might perhaps be considered in this connection.

*Arteriosclerosis of Brain and Spinal Cord, Especially in Relation to Arteriosclerosis in Other Parenchymal Vessels and to Cerebral Hemorrhage and Softening. G. Lanza.—p. 259.

Total Inversion of Viscera: Case. S. Mondolfo.—p. 338

Pseudocystic Cavities of Pellucid Septum: Pathologic Significance. F. Cottoni.—p. 349.

Arteriosclerosis of the Central Nervous System.—Lanza made an anatomic and microscopic study of the brain and spinal cord and of other structures in the bodies of seventy-five patients who died between the ages of 54 and 96 years from arteriosclerosis, vascular diseases and diseases other than vascular. The author found that arteriosclerosis of the cerebral vessels is frequent in persons over 60. The disease is more acute in the intraparenchymal than in the extraparenchymal vessels and in the nuclei of the base, especially the lenticular nucleus, than in the cerebral cortex and the spinal cord. In the cerebral cortex the lesions of the gray matter predominate over those of the white matter. Cerebral arteriosclerosis frequently exists in association with arteriosclerosis of the renal-splenic and cardiac gastrointestinal territories. The microscopic aspect of cerebral arteriosclerosis is different from that of arteriosclerosis in the parenchymal vessels of other organs. The hyperplasic delamination of the internal elastic coat of the arteries is moderate. Hyalinosis of a special type, calcification (at the globus pallidus) and arterionecrosis (at the putamen) are frequent. Arteriosclerosis of the spinal cord is more rare and less acute than that of the brain. The former frequently develops in association with the latter. Acute lesions of the wall of the vessels (arterionecrosis) exist at the nuclei of the base of the cerebral territory opposite that in which cerebral hemorrhage took place. The lesions of the nonhemorrhagic area are different from those at the hemorrhagic foci. They tend to break and to form miliary aneurysm of the Charcot-Bouchar type. The lesions of the vessels in cerebral softening follow a chronic evolution which frequently shows the most common aspect of cerebral arteriosclerosis. They tend to diminish the lumen of the vessels and to form a mechanical obstacle to circulation. The author believes that there are two different forms of cerebral arteriosclerosis. The benign form follows a chronic evolution, induces the most common aspects of cerebral arteriosclerosis in the cerebral arteries and ends in formation of cerebral softening. The malignant form follows an acute evolution, induces necrosis of the arteries and ends in cerebral hemorrhage.

60: 1-24 (Jan. 1) 1939

*Tumors of Male Breast. G. Bragagnolo.—p. 3.

Tumors of Male Breast.—Bragagnolo reports the occurrence of cancer and of fibro-adenoma of the breast in two men aged 63 and 56 respectively. The conditions are rare. An early diagnosis from the clinical examination of the patient only is difficult. Cancer of the breast develops as a rule in men over the age of 50. The clinical diagnosis is made by exclusion of several other diseases of the breast, especially tuberculosis, syphilitic gumma, chronic mastitis, fibro-adenoma and sarcoma. The tumor cannot be delimited by palpation of the breast. It is continued at some points with the surrounding tissues and joins the skin at other points by means of adhesions. It has lateral lobular nodules which can be felt by palpation of the breast. The condition may follow either a long or an acute evolution. Recurrences may or may not occur. The prognosis depends on the type of the tumor and the opportunity of an early operation, which consists in amputation of the breast and emptying of the axillary cavity. Fibro-adenoma can be delimited by palpation of the breast. The tumor forms neither adhesions to the skin nor lobular lateral nodules. The condition generally follows a benign evolution but may evolute to cancer. Therefore amputation of the breast with removal of the fascia of the large pectoral muscle is indicated. In the case of the cancer reported by the author there was no history of local trauma and of heredity and the patient did not suffer from tuberculosis or syphilis. In the case of fibro-adenoma there was a history of local trauma and of heredity. The clinical diagnosis was confirmed in both cases by the results of the microscopic study of the tumors that were removed by operation. Both patients are in good health and without recurrences (or metastases in cancer) up to now (more than three years in the case of cancer and more than one year in that of fibro-adenoma). The operation in both cases consisted in amputation of the breast followed by either emptying of the axillary cavity (cancer) or removal of the fascia of the large pectoral muscle (fibro-adenoma).

Rare Deformity of Vascular System as Cause of Attacks of Suffocation. W. Koch.—p. 63.

Bronchial Asthma in Children. J. Cirlea and L. Bogdan.—p. 65.

Vitamin C Consumption in Infants.—In the introduction to this report, Mager directs attention to the fact that C avitaminosis, scurvy, is relatively rare but that C hypovitaminosis has a high incidence. Further she discusses the vitamin C requirements of the human organism and mentions the different methods that have been recommended for the determination of this vitamin in the fluids of the body. In her own tolerance tests with vitamin C she employed the titration method by means of dichlorphenolindophenol and the litmus paper method of Scheer. All urine specimens were examined with both methods, and the comparison of the results disclosed that in most instances the results were practically identical. The tolerance tests were made on eleven nurslings and on eleven young children; a smaller or larger vitamin C deficit was detected in all of them. In nurslings the deficit was nearly always greater than in the young children. The vitamin consumption of nurslings was found to be relatively high in comparison to that of adults and it was also greater than that of young children. The vitamin C requirements of breast-fed nurslings were found to be lower than those of the bottle-fed nurslings. It was observed also that nurslings are incapable of storing vitamin C and that young children have this capacity to a limited extent. All of the children who were examined had more or less pronounced

C hypovitaminoses. The author concludes that, to prevent such conditions, care must be taken that either the food contains enough natural vitamin C or that synthetic vitamin C is administered.

*Cause of Elimination of Vitamin A in Urine. W. Thiele and K. Nemitz.—p. 95.
Hemorrhagic Diathesis in Gastric Carcinoma. O. Schildknecht.—p. 97.

Disintegration of Glycogen.—Brentano describes studies on rabbits which he carried out to determine the capacity for glycogen formation in the musculature and liver during creatinuria. In one group of animals creatinuria was induced by starvation lasting three or four days; in another group creatinuria was induced by poisoning with phlorhizin. Then the animals were given a 50 per cent solution of dextrose in a quantity that provided 10 Gm. of dextrose for each kilogram of body weight; the whole quantity was given in two equal portions rather than at once. In the second experiment the same procedure was employed except that insulin was given in addition to the dextrose. Summarizing his observations in the course of these experiments the author says that hunger and poisoning with phlorhizin produce disintegration of glycogen. Two important manifestations of this metabolic disorder are creatinuria and the impairment of the capacity to form glycogen from administered dextrose in the skeletal musculature. Insulin counteracts the creatinuria that develops during starvation and during poisoning with phlorhizin and at the same time restores the capacity of the muscle to form glycogen. Thus the disintegration of glycogen which takes place during starvation or during poisoning with phlorhizin is curable by insulin. The quantity of glycogen which is stored in the liver is reduced by the insulin because insulin apparently increases greatly the sugar requirement of the muscle. Consequently there remains less sugar for glycogen formation in the liver than is the case when sugar alone, without insulin, is administered.

Elimination of Vitamin A in Urine.—Having gained the impression that the reticulo-endothelial system is important for the storage of vitamin A and its impairment for the urinary elimination of vitamin A, Thiele and Nemitz investigated the appearance of vitamin A in the urine during diseases and during therapeutic measures in which an impairment of the reticulo-endothelial system is to be expected. They examined the urines of syphilitic patients undergoing malaria therapy and of syphilitic patients who were treated with bismuth compounds. They found that vitamin A appears in the urine during malaria as well as during the administration of bismuth compounds. Thus the assumption of a causal significance of the reticulo-endothelial system for the urinary elimination of vitamin A seems to be supported by their observations. They suggest that it might be possible to utilize the urinary elimination of vitamin A in the estimation of the function of the reticulo-endothelial system.

*Change of Specific Hypersensitivity in Hay Fever. W. Schmidt.—p. 183.

Change of Specific Hypersensitivity in Hay Fever.—Schmidt first cites reports from the literature which indicate that a change may take place in the specific hypersensitivity in patients with allergic disturbances. For instance, in persons who have changed their occupation on account of hypersensitivity to a certain substance it has been observed that, whereas the sensitivity to the substance that was the offensive agent originally has greatly subsided or entirely disappeared, a new hypersensitivity has developed to a substance with which they come in contact in their new occupation. To be sure, a period of several years generally elapses between this change in hypersensitivity. However, since such cases are rare it is generally accepted in everyday practice that allergy tests need not be repeated. In hay fever particularly it is generally accepted that the same pollen is responsible for the annually recurring attacks. The author too accepted this opinion and repeated desensitization treatments with the same allergens every year. However, some of his patients (seven in all) he tested anew for sensitivity to different pollen extracts. The results were so surprising that in spite of the small number of cases he feels justified in reporting them. On the basis of his results he differentiates four groups of patients. To the first group belong those in whom, although the specific desensitization had succeeded, a new sensitization had developed to types of pollen which formerly had given negative results. In the second group the specific desensitization was accomplished only partially. Sensitivity toward other types of pollens, which originally had produced only slight or negative reactions, had either been added to the original sensitivity or had replaced it. In the third group the attempted desensitization had failed and the sensitivity now included types of pollen which formerly had exerted no specific influence on the organism. In the fourth group the specific desensitization failed and the sensitivity toward the pathogenic types of pollens had further increased but no change had taken place in the allergen. Observations on one patient, who had received no treatment, indicated that the allergens may change spontaneously. Evaluating the practical significance of these observations, the author says that in cases of hay fever in which desensitization is not effective new tests should be made in order to detect hitherto unobserved allergens. Moreover, the annual desensitization treatment should always be preceded by new allergy tests.

Roentgenologic Examination of Liver.—Berg points out that signs of accumulation of gas in the hepatic region, particularly in the bile passages, are often detected when in the course of the roentgenologic examination of the region of the gallbladder attention is given also to the liver. He says that gas in the liver is caused by the following changes: (1) internal biliary fistulas, (2) insufficiency (gaping) of the duodenal papilla, for instance after the passage of calculi, and (3) infections of the biliary passages (cholangitis with and without abscess formation) with gas-forming micro-organisms. The author maintains that the conditions mentioned under points 1 and 3 are more frequent than has been assumed heretofore but that it is necessary to search for them. He thinks that roentgenoscopy of the liver is especially advisable in obscure hepatobiliary disorders, for instance if chronic indisposition appears after colics due to calculi, if cholangitis is followed by chills or if postoperative biliary disturbances develop. The symptom of gas in the biliary passages is of special importance in the differential diagnosis of acute abdominal symptoms, because it makes possible the early diagnosis of biliary perforation into the gastrointestinal tract. Following further discussion of these problems, the author emphasizes that roentgenologic examination of the liver, without any contrast medium whatever, may be of great value in some clinical conditions, because the symptom "gas in the bile passages" may prove to be of great diagnostic and therapeutic

value. In the second part of his paper, Berg discusses a new method of hepatolienography. He says that thorium dioxide sol has been largely abandoned as a contrast medium because it is not readily eliminated and may cause hepatic impairment. However, hepatolienography has regained its importance since a new, less harmful contrast medium has been discovered. The author describes how the new contrast medium was discovered and developed and how it is employed. The medium is an iodine sol. It is administered slowly by intravenous injection and in quantities that are computed on the basis of the body weight. Roentgenograms are made fifteen, forty-five and seventy-five minutes after the injection. At the end of twenty-four hours the contrast shadow has usually disappeared. The contrast medium is eliminated mostly in the urine in the form of an organic salt, only a small portion of it appearing in the feces. Since the iodine content of the medium may cause complications, the patient must first be tested for hypersensitivity to iodine. In about one third of the cases slight increases in temperature are observed (about 1 degree C.). Fever, chills, cyanosis or decrease in blood pressure are only rarely observed. Control examinations of patients who received injections of this contrast medium one year ago disclosed no signs of late impairment. The author thinks that some of the secondary effects of the contrast medium must be ascribed to the serious disorders (cancer, hepatic abscess, hepatic cirrhosis and so on) that exist in the examined patients. He discusses some of the most noteworthy observations that were made in the more than 100 cases that were examined with this new method of hepatolienography.

*Acute Ileus During the Years 1928 to 1938 at the Sklifasovsky Hospital. S. S. Yudin.—p. 410.

Blood Picture in Acute Ileus.—Demidova states that the blood picture in 100 cases of incarcerated hernia showed during the first few hours, before the possibility of the development of dehydration, a moderate increase of the erythrocytes and hemoglobin. The author considers this erythrocytosis to be the result of reflex stimulation of the vegetative nervous system and the outflow of red cells from the reserve depots. This was accompanied by a mild leukocytosis with a moderate shift of the neutrophils to the left. She examined the blood picture in 158 cases of acute intestinal obstruction. The blood picture here presented a marked increase in erythrocytes up to 6,000,000 and a correspondingly high hemoglobin, up to 120 per cent, a leukocytosis of from 12,000 to 30,000, a neutrophil shift to the left, hypoeosinophilia and, in a number of cases, monocytosis. A more detailed analysis showed certain differences in different types of obstructions. Obstruction of the sigmoid in twenty-five cases presented a mild erythrocytosis with a mild leukocytosis (from 9,000 to 15,000), with a moderate shift of the neutrophils to the left, a picture resembling that of the early incarcerated hernia and suggesting absence of toxemia. Ileus of the small intestine in twenty-five cases presented a blood picture with a marked increase of the erythrocytes up to 6,000,000, a leukocyte count up to 23,000 and a marked shift to the left of the neutrophils with the appearance in some cases of immature cells and of myelocytes. The leukocytosis in these toxic cases is soon replaced by leukopenia. The author concludes that the blood picture in ileus has a diagnostic value in reflecting the three stages—that of initial pain and irritation of the vegetative nervous system, that of intoxication, dehydration and thickening of the blood and that of intoxication and beginning infection (peritonitis).

Acute Ileus.—Acute ileus occupied, according to Yudin, the fifth place among the acute abdominal infections treated at the Sklifasovsky Emergency Hospital. Thus during the period from 1928 to 1938 there were treated 6,000 cases of acute appendicitis, 3,500 of extra-uterine pregnancies, 1,400 perforations of the gastroduodenal ulceration, 1,500 of incarcerated hernia and 700 of acute intestinal obstruction. While the mortality rate was markedly lowered during this period for the first four forms of acute conditions within the abdomen, that of acute ileus still presented a mortality of 35 per cent as compared with the former figure of 50 per cent. The author emphasizes the diagnostic significance of the diminution of chlorides, while pointing out that its therapeutic value is somewhat limited. The postoperative prognostic value of the chloride curve is quite definite. Cases in which the chlorides continue to fall despite all measures invariably are fatal. If, however, the chlorides increase as the result of intravenous and subcutaneous introduction of salt solution, the chances for recovery in the gravest cases are much improved. All the author's patients received 2,000 cc. of physiologic solution of sodium chloride before the operation and the same amount immediately after. An additional 3 or 4 liters is administered during the first twenty-four hours by means of the intravenous drip. The author advocates blood transfusion of from 600 to 750 cc. before the operation in order to combat shock, and another of similar amount after the operation in order to diminish the postoperative shock and to neutralize toxemia. While opposed to a universal method of anesthesia, he is partial to the spinal method, which, with proper selection of the cases and perfected technic, presents a number of advantages. He was impressed by the superiority of the radical resection of the involved intestine over the more conservative methods.

*Mental Changes in Pernicious Anemia. J. van Baalen and M. M. P. Vroon.—p. 270.
Paratyphoid A (Hepatic Form): Case. A. W. Pot and H. Verhagen.—p. 276.
*Significance of "Peculiar Appendicular Residue" in Roentgenogram. H. E. A. Fermin and G. A. Lindeboom.—p. 283.
Prophylaxis of Traumatic Neuroses. W. G. Sillevis Smitt.—p. 287.

Mental Changes in Pernicious Anemia.—Van Baalen and Vroon show that psychic disturbances may occur when changes take place in the quantity of blood as well as in diseases of the blood. Excessive loss of blood, for instance, may be followed by periods of somnolence, confusion, anxiety and headaches. Giving their attention to the mental changes in the diseases of the blood, the authors show that in polyglobulism, for instance, psychasthenic symptoms, depressive moods or even a syndrome resembling Korsakoff's psychosis may be observed. In polycythaemia rubra nervous symptoms in the form of headaches, dizziness, tinnitus aurium and paresthesias have been noted, but disturbances of a psychotic character have also been observed. Reviewing the literature on mental changes in pernicious anemia, the authors cite several investigators who have made reports about this problem and point out that Roger and Olmer differentiate three stages in the psychic disturbances of pernicious anemia. During the initial stage, mild character changes appear, such as quarrelsomeness, jealousy and peevishness. Sometimes the mental energy decreases. During the second stage there may appear various psychic changes from simple psychic asthenia to a demented condition and even delirious phases with delusions of persecution. The terminal stage is characterized by demented conditions, confusions and hallucinations. Under the influence of modern liver therapy, these disturbances are less frequent. After calling attention to some reports about psychoses in so-called funicular myelitis, the authors report their observations on three patients with pernicious anemia who had symptoms of mental disturbances. The first patient presented paranoid reactions, depressive disturbances, delirious phases and suicidal inclinations. In the two other patients, the changes in the character and in the moods predominated. As the blood picture improved under the influence of liver therapy the psychic disturbances likewise subsided.

Appendicular Residue in Roentgenogram.—Fermin and Lindeboom report that among 100 patients for whom internists had requested roentgenologic examination of the alimentary tract, twenty-seven showed an "isolated" appendicular residue (shadow in the appendix and not in the cecum) after forty-eight hours. None of these patients were later found to have chronic appendicitis. Many of them had symptoms of ulcer. In two of the cases the anamnesis or the examination disclosed signs indicative of chronic appendicitis and the authors think

that these were the only cases in which appendectomy was indicated. Later the authors examined twenty-four persons in whom an x-ray examination of the alimentary tract had not been requested and who were free from abdominal symptoms. They found that four of this group showed an isolated appendicular residue after forty-eight hours. They conclude from these observations that the isolated appendicular residue is of no great value in determining the advisability of an appendectomy. In this regard the phenomenon probably acquires greater importance if it is observed after a longer period; that is, after four days.

Appearance and Frequency of Desquamation in Scarlet Fever. L.-G. Sterner.—p. 280.

Mastic Test in Acute Anterior Poliomyelitis.—Kaijser says that little attention has been given to the mastic reaction in acute anterior poliomyelitis. Nevertheless, several observers have shown that a type of mastic reaction can be evolved which is characteristic for poliomyelitis. The mastic test has been employed in experimental poliomyelitis in monkeys as well as for the early diagnosis of poliomyelitis in human subjects. The author himself studied the value of the test first in fourteen cases of acute anterior poliomyelitis accompanied by paralysis. He reports the clinical histories of these cases and the outcome of the mastic reaction. It was found that in certain cases of poliomyelitis in which paralysis exists at the time of the examination of the cerebrospinal fluid there is a typical mastic reaction. In the majority of these cases only a moderate flocculation was observed in the tube that contains the strongest concentration and the maximum of flocculation appeared in the second, third and fourth tubes. In the succeeding tubes it subsided and it usually disappeared completely in the sixth or seventh tube. The average curve of the mastic reaction in these cases is represented by the figures 123321000. Having determined that poliomyelitis with paralysis possesses a typical curve, the author studied the mastic reaction in two other types of disorders, namely in ten cases of acute anterior poliomyelitis without paralysis and in five cases in which poliomyelitis was suspected. In the ten abortive cases of poliomyelitis the curve of the mastic reaction was not as uniform or as characteristic as in the cases of poliomyelitis that were accompanied by paralysis. In the abortive cases the maximum flocculation was usually observed in tubes 2, 3 and 4. In the five cases in which poliomyelitis was only suspected, the mastic reaction was as it is under normal conditions. The impression was gained that in these five cases there existed a disorder other than poliomyelitis.

Serotherapy of Lobar Pneumonia.—Nissen gives an account of the serum treatment of lobar pneumonia in the Sundby Hospital in Copenhagen and presents statistical data on cases treated with or without serum in the municipal hospitals of Copenhagen in the period from October 1935 to May 1938. Until the autumn of 1937 the serum treatment was given almost exclusively with horse serum, but since November of that year rabbit serum has been generally used. It was found that when adequate serum treatment is given within the first four days of illness a case mortality of more than 40 per cent can be lowered to less than 10 per cent; when treatment with large doses of serum is instituted on the fifth and sixth day, the mortality may probably be reduced to less than 20 per cent. Even on the seventh day the treatment ought to be tried in severe cases. Treatment with serum not specific for the type gave a lower mortality than treatment without serum, but a typical reduction of temperature was rare after administration of such serum. The therapeutic efficacy of nonconcentrated rabbit antipneumococcus serum is just as great as that of concentrated horse serum; whether it is superior cannot be decided on the basis of the present material. The failure of type specific serum treatment may be due to (1) too late institution of treatment owing to belated clinical or bacteriologic diagnosis, (2) infection with more than one pneumococcus or mixed infection with other bacteria, (3) insufficient dosage, (4) poor quality of serum, (5) bacteremia, (6) preexisting complications, especially cardiac and pulmonary lesions, pregnancy, cirrhosis of the liver, and syphilis and (7) pneumonic complications in the lungs, heart, meninges and peritoneum. Finally, cases will occur in which the infection is so violent from the start that all specific therapy is ineffective. Serum shock was seen in only 5 to 7 per cent of the cases, collapse after one of 222 primary serum injections. Serum shock was not more frequent or more severe, but rather less frequent, after the nonconcentrated rabbit serum preparations than after concentrated horse serum. Serum sickness was far less frequent after the use of concentrated horse serum than after nonconcentrated rabbit serum, occurring respectively in 21 per cent and 47 per cent of the patients, and it was more severe in the patients treated with rabbit serum. Most likely, concentration of the rabbit serum will lower the incidence and intensity of serum sickness. Purulent lung complications were not more frequent in patients treated with serum than in those treated without serum, rather less frequent. The absolute numbers are bound to be somewhat uncertain, because necropsy was not permitted in many of the fatal cases.

*Observations on Action of Aminopyrine on Living Neutrophile Granulocytes in Normal Persons and in Persons Hypersensitive to Aminopyrine. I. Wallgren.—p. 560.
Approximate Determination of Fat Content in Feces. R. Ehrström.—p. 577.
Blood Picture in Intracutaneous Vaccination. Birgitta Knape.—p. 579.

Action of Aminopyrine on Granulocytes.—Examining neutrophil granulocytes in a milieu with successively increased aminopyrine content, Wallgren established a threshold at which most of the cells still performed their ameboid movements and a higher threshold at which most of the cells no longer moved. In cells from normal persons the upper threshold was at an aminopyrine concentration of from 0.2 to 0.24 per cent in cells from two persons hypersensitive to aminopyrine at a concentration of 0.14 and 0.18 per cent respectively. He says that in hypersensitive persons, after the intake of aminopyrine, there is in addition to other symptoms a decrease in the number of neutrophil granulocytes in the peripheral blood. Since the neutrophil granulocytes in vitro withstand an aminopyrine content many times higher than that which appears in the blood plasma after the usual therapeutic dose of aminopyrine, it is not likely that this dose causes a disturbance of the cells in the circulating blood. The occurrence of neutrophil granulocytes in the circulating blood is variable. Leukopenia may occur in the peripheral blood simultaneously with a leukocytosis in the internal organs, and vice versa. In conditions of shock there may be a sudden transport of neutrophil granulocytes from the skin to the internal blood vessels. It does not seem unlikely that the sudden leukopenia which appears in hypersensitive persons after aminopyrine medication takes place in the same way. This presupposes an abnormal sensitivity in the mechanism which regulates the apportionment of the neutrophil granulocytes in the blood vessel system. The fact that the cells from persons hypersensitive to aminopyrine cease their ameboid movements at a lower threshold than do the cells from the control cases may be the expression of such a hypersensitivity in the apportionment mechanism of the neutrophil granulocytes.

*Iron Content in Liver in Pernicious Anemia After Some Improvement Following Short Treatment with Liver. C. A. Hernberg.—p. 647.
Two Cases of Unilateral, Partial Aplasia of Adnexa. N. Riska.—p. 651.
Some Cases of Tetany Treated with Dihydrotachysterol. S. Söderlund. —p. 659.

Iron Content of Liver in Pernicious Anemia.—Hernberg states that in a woman aged 60, who died from bronchopneumonia on the tenth day after the start of energetic liver treatment, the hemoglobin content had risen from 23 to 36 per cent, the number of red blood corpuscles had risen from 824,000 to 1,640,000, and the color index had dropped from 1.64 to 1.1. The liver showed a definite siderosis. The total iron in the liver was 637.5 mg., more than six times as much as that previously found by the author in two cases of pernicious anemia in full remission.

MODERN METHODS OF TREATMENT OF DISEASES OF THE NERVOUS SYSTEM

TRACY J. PUTNAM, M.D.

BOSTON

It has not been many years since neurology was widely considered a purely diagnostic specialty—a *meditatio morbis*. One can look through the pages devoted to nervous diseases in almost any textbook of medicine written before the war and find scarcely a single suggestion of treatment beyond arsenic, strychnine, bromides and electricity, aside from the more obvious indications for surgery.

Yet there are specific and effective forms of treatment for neurologic diseases, and their number has shown an astonishing growth during recent years. Since so few of them have found their way into the common body of medicine, I have thought it might be of interest to review them. In assembling such a summary, I find that as a matter of fact there is so much ground to cover that certain important territories will have to be omitted entirely.

Three large and significant fields about which I shall say little are surgical. They are the territories of the treatment of injuries of the nervous system, of the surgery of tumors and of operations on the sympathetic system. Any brief summary would fail to do them justice; moreover, the story of their successes has often been brought before the medical public, and recent authoritative books are available on each.[1]

I shall leave psychiatry and psychotherapy entirely out of account as being outside my own sphere of competence. In passing, however, I should like to pay tribute to the rising standard of psychologic understanding and interest among practitioners and students of today. Though startling innovations have been rare, there is far less quarreling over doctrinal differences and far more devotion to an unprejudiced appraisal of the patient's needs of various kinds than was the case twenty years ago.[2]

In addition to these intentional omissions there are, I am sure, unintentional ones. This list of methods of treatment makes no pretensions to completeness. It consists of those which seem thoroughly established or with which I have had personal successful experience. An attempt has been made to give credit only for broad innovations, but I am quite aware that the story might have been written with an entirely different set of heroes. It is the theme that I particularly wish to bring to attention.

THE TREATMENT OF PAIN

To return to more strictly neurologic subjects: It is perhaps natural that pain should be the symptom of disease of nerve tissue which earliest demanded and first received specific relief. The use of opium dates back to prehistoric days and no real substitute for it has ever been found. According to Létiévant [3] the first recorded nerve section for neuralgia was performed by Maréchal, the court surgeon of Louis XIV. I have not been able to find any particulars. Létiévant himself, writing in 1872, was familiar with section of branches of the trigeminal, the intercostals, the occipitals and the sciatic nerves. Peripheral neurectomies have, however, largely fallen out of use except in the treatment of supra-orbital neuralgia, of thrombo-angiitis obliterans [4] and of tuberculosis of the larynx.

A more refined procedure is intraspinal section of spinal posterior roots, first suggested by Charles Dana and carried out by Robert Abbe [5] of New York in 1888. This obviously has the advantage that motor power is preserved. It paved the way for that triumph of surgery, the radical cure of trigeminal neuralgia. Rose [6] was the pioneer in removal of the gasserian ganglion, but his approach has been abandoned. Horsley [7] cut the posterior root by a method resembling the modern one in 1891 but his patient died. Successful results from a practical procedure were announced by Krause [8] in 1893.

A bold step forward in neurologic treatment was suggested by Schüller in 1910 [9] and carried out by Spiller and Martin [10] in 1911, the section of the pathways for pain in the spinal cord. Aside from the prac-

tical value of the operation, which has now become a common and standard one, this step opened what promises to be an important epoch in neurology, that of operative intervention on structures of the central nervous system for the purpose of altering its physiology.

Except for operations on the sympathetic nervous system, which will be mentioned briefly later, the only new procedure for the relief of pain which has found wide acceptance is that introduced by Dogliotti [11] in 1931, namely the subarachnoid injection of absolute alcohol. The method was first used in this country at the Neurological Unit, as far as I am aware, and the staff has convinced itself that the method has definite though restricted value. It is a conservative method of treating mild chronic pain; for severer conditions chordotomy saves time, pain, uncertainty and the patient's motor power. A field of usefulness for the procedure of Dogliotti which deserves further study is in the treatment of certain forms of spasticity.

SURGICAL TREATMENT OF TUMORS OF THE NERVOUS SYSTEM

The first successful operation for tumor of the brain (by Godlee) was recorded in 1884.[12] A tumor of the spinal cord was removed in 1888 by Horsley.[13] Annandale [14] reported recovery after operation on an acoustic neuroma in 1893. Successful radiotherapy of a pituitary adenoma was reported by Béclère [15] in 1901. Nordentoft [16] announced successful treatment of gliomas in 1917. From these hesitating beginnings the surgery of tumors of the brain and spinal cord has made enormous strides, perhaps most strikingly signalized by Cushing's [1] review of his 2,000 verified tumors in 1932. I shall make no attempt to trace the steps of the progress, but I should like to point out that it was due largely to the successes of tumor surgery that hopes of successful forms of treatment in other departments of neurology were aroused.

THE TREATMENT OF CONVULSIONS

Epilepsy was recognized as a disease and treated in prehistoric times. While scattered "cures" have followed the use of any one of a thousand different remedies, only a few measures have come to be accepted in modern practice. One of these is the use of bromides. This was apparently first recommended by Sir Charles Locock [17] in 1857 in the course of a discussion of a paper by Sieveling. Locock's reasoning was simple: An unnamed German had tried potassium bromide on himself and found it an anaphrodisiac; it was well known that many cases of epilepsy were caused by onanism; he tried it in fourteen cases and it worked in all but one. It is still recognized as a moderately successful anticonvulsant.

A rational operative treatment for focal epilepsy was reported by Horsley.[18] in 1887, namely excision of an irritable focus of the cortex. The procedure could scarcely be termed an accepted one until after the careful studies of Foerster and Penfield.[19] It appears probable that the more precise information which can now be obtained by electro-encephalography will be of particular value in selecting cases for this treatment.[20]

On the whole, the most successful treatment for the majority of patients suffering from convulsions of unknown origin is the use of phenobarbital, which was recommended for this purpose by Hauptmann [21] in 1912. It is applicable to a far larger proportion of cases than is surgery, and it has a greater anticonvulsant effect in proportion to its soporific effect than bromides or than any of the other barbiturates.

The treatment of epilepsy by ketosis was reported by Wilder [22] in 1921. It is a measure which still finds employment in some cases, particularly for petit mal in children.

The drugs at present in use for the treatment of convulsions were all primarily introduced as hypnotics, and the discovery of their anticonvulsant effect has been rather accidental. A systematic search for anticonvulsants by an experimental method was begun at the Neurological Unit in 1937 [23] and is still being continued It has already yielded one compound, diphenylhydantoin, which appears to be more effective than phenobarbital and without appreciable soporific effect. The study of convulsions by means of electro-encephalography [20] suggests that there are several types, each due to a distinct physiologic mechanism, and possibly each will require individual study and treatment.

TREATMENT OF NEUROSYPHILIS

The recognition of syphilis of the nervous system is a relatively modern feat. It was doubtless treated with mercury even before it was recognized. According to Garrison,[24] the identity of the man who first introduced mercury into therapeutics is unknown. It is probable that, as far as neurosyphilis at least is concerned, its reign is almost over.

The story of the introduction of arsphenamine by Ehrlich [25] in 1910 is familiar to all. It is unique in history—a new conception systematically and patiently pursued by a great genius over many years, and finally a magnificent success—to be compared only with vaccination in its significance to the human race. As a treatment for parenchymatous neurosyphilis it has largely been replaced by a modification—tryparsamide,

prepared by Jacobs and Heidelberger [26] of the Rockefeller Institute in 1917. The use of fever in the treatment of neurosyphilis has a long history in the life of one man. Wagner von Jauregg [28] apparently first noticed its effect in dementia paralytica in 1887 but he dropped the subject and returned to it only during the war. His first brief paper specifically recommending the use of malaria was published in 1918.[29] Since then the method has become a standard one.

A few years later the use of bismuth was proposed by Sazerac and Levaditi.[30] The salts of this metal have largely taken the place of those of mercury.

At the turn of the century there was no known method of treatment of syphilis that would prevent infection of the nervous system. Up to the close of the war, once neurosyphilis was established, there was little hope of arresting its course. At present the majority of early cases can be cured.

THE TREATMENT OF OTHER INFECTIONS

Among infections of the nervous system, abscess of the brain presents a problem of which the solution is obvious but difficult to attain. Successful operation on an abscess was reported by Morand [31] in 1768. The principles governing operative treatment are gaining slow recognition and there has been a gradual decline in the average operative mortality.

The next progress in controlling infections came with the rapid growth of bacteriology and immunology in the last quarter of the last century. The Pasteur prophylaxis against rabies [32] in 1885 and the antitoxin against tetanus developed by von Behring [33] in 1892 are now so successful that one can scarcely reconstruct for oneself the days when those terrible diseases were common.

Meningitis, next to syphilis the most common form of infection of the nervous system, still retains a high rate of mortality. The value of lumbar puncture in its treatment [34] is not yet fully recognized. A specific antiserum against infections with the meningococcus was introduced by Jochmann [35] in 1906. Although widely used, its value is still in some doubt. In the last two years, synthetic drugs of the type of sulfanilamide [36] have become a standard treatment, which is amazingly effective not only against infections by the meningococcus but against other pyogenic infections.

There is no accepted treatment for, or prophylaxis against, poliomyelitis, encephalitis and herpes. It has been shown that many types of "encephalitis" are in reality not infections of the brain.[37] Severe chorea of the Sydenham type, and also that occurring in pregnancy, may be effectively treated by induced fever.[38] The severe neuralgia that sometimes follows herpes usually yields to roentgen treatment.[39]

TREATMENT OF DEFICIENCY DISEASES

An increasing number of diseases of the nervous system are now being recognized as due to vitamin deficiency. The first of these was pellagra,[40] the treatment of which has now been placed on a sound basis.[41] Modern vitaminology may be said to have begun with Eijkman's [42] experiments on beriberi. He would have been surprised, perhaps, to see most polyneuritides regarded as subvarieties of beriberi,[43] including the type described by Landry.[44]

Owing to the recognition that combined systemic disease of the spinal cord is related to pernicious anemia, it is obvious that Minot and Murphy's discovery of the liver diet for the treatment of the latter should be applied to the former also. There have been disappointing results with liver treatment in some hands, but convincing evidence has been offered that arrest of progress of degeneration of the cord is the rule, and improvement is common if large enough doses are used—far larger than are needed to control the blood picture.[45]

Not only "alcoholic" polyneuritis [46] but also the characteristic confabulatory psychosis often associated with it appears to be due in part to a vitamin deficiency.[47] It is likely that the same is true of Wernicke's alcoholic poliencephalitis.[48] How effective treatment of these conditions will be remains to be seen.

TREATMENT OF DISEASES OF THE SYMPATHETIC SYSTEM

Surgery of the sympathetic nervous system had its beginnings in the last century, but its real successes have come only since the war. It is of definite value in the treatment of Raynaud's disease [49] and of Hirschsprung's disease.[50]

There have been many disappointments in the treatment of angina pectoris, but alcohol injection of the intercostal nerves as carried out by Mandl [51] appears to be a reliable method of cure of the pain. Certain obscure painful conditions of the extremities are some-

times benefited by sympathectomy.[52] Further information should be sought in one of the recent treatises on the subject.[1c]

A recent accession to the list of conditions amenable to surgery is the carotid sinus syndrome. The clinical importance of the condition has been pointed out by Weiss[53] and the possibility of its surgical relief has been demonstrated at the Boston City Hospital.

Whether or not migraine should be included among surgical diseases is open to question. Cervical sympathectomy,[54] injection of alcohol into the gasserian ganglion,[55] section of the temporal artery and of the meningeal artery[56] have all been followed by success in some instances and failure in others. A remarkable medical treatment for individual attacks of migraine is the use of ergotamine tartrate.[57]

THE TREATMENT OF PARALYSIS AGITANS AND ATHETOSIS

One of the most familiar diseases of the nervous system is paralysis agitans. The only accepted treatment for this often distressing condition is the use of drugs of the atropine series, apparently first suggested by Charcot.[58] Enormous doses are sometimes tolerated but are often ineffective. Recently the use of a fresh hot decoction in white wine has found wide and apparently successful use in Italy. Some of my patients have told me that moderate doses of alcohol, alone or with scopolamine, are valuable. The asthenia that often accompanies the disease may sometimes be relieved in the postencephalitic types of paralysis agitans by administration of amphetamine (benzedrine) sulfate,[59] which is also a fairly reliable remedy for the oculogyric crises which accompany it.

In extremely severe unilateral cases the resort to surgery may be justified. Bucy[60] has recently demonstrated that the tremor may be abolished by an extensive resection of the motor cortex—a possibility vaguely foreshadowed by Parkinson himself.[61] At the Neurological Unit a similar result has been obtained by section of the pyramidal tract in the spinal cord, which impairs the function of the corresponding limbs to an astonishingly slight extent.[62]

The somewhat rarer but often far more distressing condition of athetosis has received less attention than it deserves. The first successful attempt at its relief, excision of the corresponding motor cortex, was reported in 1909 by Horsley,[63] and his method has been further developed by Bucy and his associates.[64] The method first used at the Neurological Unit in 1931 accomplishes the same object by section of the extrapyramidal tracts in the spinal cord.[65] It can be used in bilateral cases (best in two stages) and does not destroy the use of the extremities.

A promising start in the medical treatment of athetosis has been made by West.[66] He has shown that the intravenous administration of curare will depress abnormal movements for several days, and this has been confirmed by Burman[67] and at the Neurological Unit. Obviously, the method is not suitable for general use at present, but a search for more practical drugs is under way.

The most successful treatment for spasmodic torticollis is the operation devised by Dandy:[68] section of the first four cervical roots and the spinal accessories.

THE TREATMENT OF HYDROCEPHALUS

The importance of hydrocephalus as a disease has been underestimated. According to Murphy[69] it occurs in the proportion of more than one and one-half times in every thousand "white" births; that is, there are probably two or three thousand hydrocephalic infants born every year in this country. Most hydrocephalic infants are mentally defective from the outset, and these are doomed in any case. Many of them, however, —perhaps a fourth—are apparently capable of growing up normally if the pressure can be relieved. There have been isolated successes from various types of operations (reviewed by Davidoff[70]), but only recently have technical improvements permitted a series large enough for statistical purposes to be accumulated.[71] In selected cases the operative mortality may be as low as 10 per cent after bipolar coagulation of the choroid plexuses. When hydrocephalus and spina bifida coexist, an alternative method of relief has been successful in a few instances, namely resection of the abnormal mass of tissue which apparently blocks the circulation of fluid.[72]

TREATMENT OF SYRINGOMYELIA

Syringomyelia is a hereditary malformation which often exists without giving rise to symptoms. About 60 per cent of cases are improved by persistent treatment with x-rays.[73] In cases resistant to irradiation

and especially those in which there is pain or a subarachnoid block, operative drainage of the syrinx may afford some relief. This operation was first recorded by Elsberg [74] and was applied in a systematic fashion and recommended by Puussepp [75] of Estonia, where the condition is apparently far more common than in this country.

TREATMENT OF MÉNIÈRE'S SYNDROME

A method of treatment of recurrent attacks of vertigo, by destruction of the labyrinths, was suggested by Lake [76] in 1904. The operation of section of the auditory nerve was first carried out by Frazier [77] in 1910. Both types of procedure were long neglected and have only recently come into their rightful places.[78] In addition to the modern operations, medical treatment, which is often effective, has been proposed by Furstenberg.[79]

NEW MEDICAL REMEDIES FOR MISCELLANEOUS DISEASES

Narcolepsy is a disease which is often overlooked or untreated. The overpowering drowsiness which characterizes it is satisfactorily combated by amphetamine sulfate, for which the patients often have a high tolerance.[80] Since the introduction of the drug for this purpose it has been widely used in the treatment of asthenia, fatigue and debility of many types [81] perhaps too widely, for it is not a drug for indiscriminate use.

An effective treatment for myasthenia gravis was found by Mary Walker [82] in 1935, namely prostigmine, a synthetic substitute for physostigmine.[83] Myotonia, a disease which is in many ways the opposite of myasthenia (both are apparently disorders of the chemical transmission of the nerve impulse), was relieved by the use of quinine by Kennedy and Wolf [84] in 1936.

TWO MECHANICAL SUBSTITUTES FOR NERVOUS FUNCTIONS

There are many disease states which produce a temporary cessation of respiration but are not necessarily fatal otherwise. A respirator was designed by Drinker [85] in 1929 primarily for use in resuscitation from asphyxia and electric shock. It is, however, finding a larger and constantly expanding use in the treatment of poliomyelitis, polyneuritis and injuries to the spinal cord. A respirator should be part of the equipment of every neurologic service.

Many deaths have resulted from infection of the bladder and kidneys following disease of the spinal cord. A practical device for preventing cystitis was devised by Laver and perfected by Munro in 1934,[86] namely a tidal drainage apparatus on the principle of a Tantalus siphon. The importance of the apparatus extends far beyond the comfort of the patient and the saving in bed linen. The prevention of infection permits a degree of recovery of damaged nerve tissue which would never be possible otherwise. It is simple and inexpensive and should be available in every hospital.

THE PROSPECT OF FURTHER ADVANCES

Since the war, and especially during the past ten years, something of a revolution has taken place in the field of clinical neurology. From a static branch of medicine, with the ideal of predicting irreversible structural changes from rigidly classified syndromes, it has become more dynamic by advancing in two directions. One is toward interpretation of the activities of an injured nervous system in terms of neurophysiology and thence toward remedying the defect. Examples of this type of analysis and systematic attempts at applications of physiologic knowledge are the recent steps forward in the treatment of epilepsy, paralysis agitans and athetosis, and longer strides in the same directions are unquestionably in prospect.

Another type of dynamic concept which is relatively new in neurology is an analysis of the mechanism and pathogenesis of diseases of the nervous system. The gross and microscopic appearances of the brain and cord in practically all diseases known today were described before the turn of the century. The stages in breakdown of various tissue elements have been thoroughly studied. Attention is now centered on the steps preceding irreparable damage. Arteriosclerosis and neurosyphilis were probably the first diseases in which attempts at dynamic interpretation were made and are still being continued. The mechanism and pathogenesis of multiple sclerosis, next to neurosyphilis and epilepsy the most important disease of the nervous system, are now fairly clear.[87] Similar advances in the pathology of the deficiency diseases,[88] progressive muscular atrophy [88] and amyotrophic lateral sclerosis [88] are in progress and in the course of time will certainly bear fruit.

The practical understanding and treatment of nervous and mental diseases are still in an expanding stage. The subject grows more complicated with each year that passes, and while there is a proper tendency for diseases formerly considered to lie within the jurisdiction of the neurologist to pass into the hands of internists and general surgeons—for example tetany and hyperthyroidism—the specialized knowledge and interest of trained neurologists, provided with adequate and independent facilities for research, is essential for real progress in the comprehension of many obscure and intricate problems. To reduce clinical neurology to a subdepartment is to subordinate the welfare of patients suffering from diseases of the nervous system.

EFFECT OF ALCOHOL ON NORMAL KIDNEY AND KIDNEY OF BRIGHT'S DISEASE

AN EXPERIMENTAL STUDY

MAURICE BRUGER, M.D.
S. ARTHUR LOCALIO, M.D.
AND
NOBEL W. GUTHRIE, M.D.
NEW YORK

THE EXCRETION OF ALCOHOL BY THE KIDNEY

Alcohol is assumed frequently to be a renal irritant, although the amount eliminated by the kidney after its ingestion is relatively small. Miles [1] has shown that after a single dose of alcohol (about 0.5 cc. per kilogram of body weight) in a human being only 1.2 to 1.6 per cent of the amount ingested is excreted within the first two hours. In the next six hours approximately 0.3 per cent is excreted; the urine is practically alcohol free in eight hours. Haggard and Greenberg [2] have shown that in dogs the percentage of the total amount of alcohol lost through the kidneys depends on the quantity of urine passed and that in sixteen hours varies from 2.4 to 4.3 per cent of the alcohol ingested. These values confirm the earlier work of Binz,[3] Heubach [4] and others.[5] In a fatal case of alcohol poisoning, Juckenack [6] found the concentration of alcohol in the kidney to be 0.37 per cent and in the urine 0.65 per cent.

ALCOHOL AND BRIGHT'S DISEASE

In 1932 Langmead and Hunt [7] said "The drinker undoubtedly shows some increasing susceptibility to inflammation of the kidney (Bright's disease). . . . Whatever the causal mechanism, there is abundant clinical experience that alcohol may promote chronic nephritis." The treatise in which this statement occurred carried an editorial footnote to the effect that this opinion is not held in this country and that it is not known that alcohol causes chronic nephritis, although its use may aggravate the symptoms of the disease. In 1924 Vogelius [8] wrote that "very few authors deny the importance of alcohol intoxication in the occurrence of renal disease." Of the forty-two patients with chronic alcoholism studied by Vogelius, tests of renal function revealed the presence of renal disease in twenty. Scheel [9] stated that alcoholism in conjunction with other factors may contribute to the development of true contracted kidney. Zundell, Volhard and Strauss [9] maintained that alcohol exerted a definite influence on the kidney; its use in acute nephritis was absolutely forbidden, whereas in the chronic forms the restriction was less severe. Von Noorden [9] prescribed alcohol for nephritic patients only when the appetite had to be increased or the heart stimulated. In 1926 MacNider [10] studied the effect of alcohol and of alcoholic beverages on the kidneys of normal and of naturally nephropathic dogs. He found that in normal dogs alcohol was only slightly nephrotoxic whereas naturally nephropathic dogs were more susceptible to the toxic effect of the same amount of alcohol; moreover, both the normal dogs and the dogs with renal disease showed an increased toxicity to alcoholic distillates. Moschini [11] reported a case of nephrosis in a nursing infant of 4 months in whom the renal lesion, according to this writer, was due to alcoholism of the mother.

However, a number of authors have published data indicating that alcohol does not initiate or aggravate renal disease. Friedenwald [12] fed a large series of rabbits somewhat excessive doses of either alcohol or whisky daily to the point of intoxication. Although a small number of these animals began to show albumin and casts in the urine after two months of such treatment, the pathologic changes thus produced in the kidney were unlike those seen in chronic nephritis. In 1910 Hultgen [13] investigated 460 patients with chronic alcoholism and showed that only 9.1 per cent of these manifested any evidence of nephritis. Moreover, only 5.2 per cent of the 460 drinkers showed any permanent albuminuria. He concluded that alcohol taken daily, as it is by the chronic inebriate, is not an irritant to the kidneys. Wegelin [14] reported definite changes in the kidney in only seven of 106 chronic alcoholic addicts Ziegler and Horner,[15] in a recent pathologic study of twenty chronic alcoholic addicts, found only slight glomerular lesions in 20 per cent. Mosenthal [16] maintained that alcohol does not damage the renal parenchyma and that it may be prescribed without hesitation in renal disorders, even when patients are seriously ill. Masci [17] reported an interesting case of acute nephritis in a 41 year old man, who, tired of his restricted regimen, imbibed 2,500 cc. of white wine in three hours Anuria developed, lasting for twenty-four hours; this was followed by the excretion of markedly hemorrhagic urine. The patient, however, began to improve readily and within ten days after the ingestion of the wine was pronounced cured. The urine was protein free and con-

tained no red blood cells or casts. The permanence of the cure was proved by a recheck several months later.

In view of the somewhat conflicting evidence as to the effect of alcohol and of alcoholic beverages on the normal and the diseased kidney, it seemed worth while to reinvestigate this problem, since accurate methods are available today for studying the degree of irritation and functional capacity of the kidneys.

MATERIAL AND METHODS

Twenty-one subjects have been studied, of whom five were free from renal disease, five had acute diffuse glomerular nephritis, seven had chronic diffuse glomerular nephritis and five had arteriosclerotic nephritis (nephrosclerosis). All subjects were kept at complete bed rest. The diet was kept constant throughout the course of study. Addis counts [18] were carried out on twelve hour specimens of urine voided from 7 p. m. to 7 a. m. It was impossible to precede this period by a twelve hour dry diet, as suggested by Addis, since in many cases the restriction of fluid was contraindicated and at other times alcohol was given. For this reason patients were placed on a dry diet three hours prior to the twelve hour collection of urine. Addis counts were carried out daily for from three to five or more days, until the number of formed elements in the urinary sediment exhibited some degree of consistency. Urinary volume was carefully measured, the protein excretion determined [19] and the reaction of the urine noted. After control Addis counts showed satisfactory agreement, an experimental day was set aside in which two determinations of urea clearance [20] covering two hours each were carried out before and immediately after the ingestion of alcohol. The amount of alcohol given varied from 50 to 200 cc. of a 25 per cent solution by volume of pure ethyl alcohol or of distilled bonded whisky in amounts equivalent to 100 or 200 cc. of 25 per cent pure ethyl alcohol. After the larger doses, signs of intoxication were invariably present, though only to a mild degree. Specimens of blood were analyzed for urea nitrogen [21] and nonprotein nitrogen,[22] and the urea ratio [23] was calculated. The alcohol content of the blood was also determined.[24] On the day on which the alcohol was given the dry diet, starting at 4 p. m., was resumed and the urine collected from 7 p. m. to 7 a. m. the following day. On the following day, if alcohol was again taken, the urea clearance was determined before and after. However, if no alcohol was given on this particular day, the urea clearance was again determined in the afternoon. In most cases Addis counts were carried out for several days after the ingestion of one or more doses of alcohol.

TABLE 1.—*The Immediate Effect of Alcohol and of Alcoholic Liquors on the Normal Kidney and on the Kidney of Bright's Disease*

Case	Age	Sex	Alcohol Ingested: Type	Alcohol Ingested: Quantity	Positive Results
				Normal Group	
3	26	♂	Alcohol	200 cc 25% solution	Diuresis, urine red blood cells and white blood cells increased but not above normal; blood urea nitrogen slightly increased
6	42	♀	Alcohol	200 cc 25% solution	Diuresis; urine red blood cells increased but not above normal, white blood cells and casts increased above normal; blood: urea nitrogen and urea ratio slightly increased; urea clearance increased
9	20	♀	Alcohol	200 cc 25% solution	No significant effects
10	35	♂	Alcohol	200 cc 25% solution	Urea clearance increased
11	16	♂	Alcohol	50 cc. and 100 cc 25% solution in 48 hours	Diuresis, Urine: red blood cells, white blood cells and casts increased but not above normal
				Group with Acute Diffuse Glomerular Nephritis	
2	44	♂	Alcohol	2 doses of 200 cc. 25% solution in 24 hours	Diuresis; proteinuria increased; urine: red blood cells, white blood cells and casts increased; blood. urea nitrogen and nonprotein nitrogen increased
16	30	♂	Scotch whisky	57 5 and 115 cc in 24 hours, equivalent to 100 cc and 200 cc 25% solution of alcohol	Slight diuresis, blood. urea nitrogen and nonprotein nitrogen increased
19	29	♂	Rye whisky	50 and 100 cc in 24 hours, equivalent to 100 cc and 200 cc 25% solution of alcohol	Diuresis; blood: urea nitrogen increased slightly after first dose of alcohol but decreased after second; urea clearance decreased after first dose of alcohol but increased after second
21	30	♂	Rye whisky	50 and 100 cc in 24 hours, equivalent to 100 cc. and 200 cc 25% solution of alcohol	Urine consistent decrease in red blood cells, white blood cells and casts not impaired by ingestion of whisky, blood: urea nitrogen and nonprotein nitrogen decreased
				Group with Chronic Diffuse Glomerular Nephritis	
7	23	♂	Alcohol	200 cc 25% solution	No significant effects
8	33	♀	Alcohol	200 cc 25% solution	Blood urea nitrogen decreased; urea clearance increased
12	25	♂	Alcohol	50 cc and 100 cc 25% solution in 24 hours	Diuresis; blood. urea nitrogen and urea ratio decreased, urea clearance increased
13	42	♀	Alcohol	50 cc 25% solution	Diuresis; urea clearance slightly decreased
14	17	♂	Alcohol	50 cc and 100 cc 25% solution in 24 hours	Diuresis; blood urea nitrogen increased; urea clearance decreased
15	15	♀	Scotch whisky	2 doses of 57 5 cc in 24 hours, equivalent to 100 cc 25% solution of alcohol each	Urine red blood cells and casts decreased, urea clearance temporarily decreased
17	50	♂	Rye whisky	50 cc and 100 cc in 24 hours, equivalent to 100 cc and 200 cc 25% solution of alcohol	Diuresis after second dose only; proteinuria increased
				Group with Arteriosclerotic Nephritis	
1	62	♂	Alcohol	2 doses of 200 cc 25% solution in 24 hours	Diuresis, proteinuria increased; urine red blood cells and white blood cells increased; urea clearance decreased
4	41	♀	Alcohol	200 cc 25% solution	Urine casts increased; urea clearance decreased
5	52	♀	Alcohol	200 cc 25% solution	Blood urea nitrogen increased; urea clearance decreased
18	50	♂	Rye whisky	50 cc and 100 cc in 24 hours, equivalent to 100 cc and 200 cc 25% solution of alcohol	Urine red blood cells and casts increased
20	44	♂	Rye whisky	50 cc and 100 cc in 24 hours, equivalent to 100 cc and 200 cc 25% solution of alcohol	Diuresis; urine: red blood cells, white blood cells and casts increased; urea clearance decreased

RESULTS

The pertinent data and positive observations in all cases are given in table 1. The results may be summarized briefly as follows: 1. In subjects with normal

18 Addis, Thomas A Clinical Classification of Bright's Diseases, J A. M A 85: 163 (July 18) 1925

kidneys the ingestion of alcohol was occasionally followed by an increase in the excretion of red blood cells, white blood cells and casts in the urine, but the values were rarely elevated above the average normal range. Proteinuria was not induced, nor did any measurable impairment of renal function occur. 2. Alcohol rarely augmented the proteinuria in patients with Bright's disease. 3. Moderate diuresis was frequently induced (this occurred even in patients with marked impairment of renal function). 4. Alcohol did not increase the number of red blood cells and casts in the urine of persons with acute diffuse glomerular nephritis (with the exception of patient 2) or of patients with chronic diffuse glomerular nephritis. The ingestion of alcohol or whisky by patients with arteriosclerotic nephritis (nephrosclerosis) produced a transient increase in the Addis count (with the exception of patient 5). 5. The renal function remained unchanged after the ingestion of alcohol by persons with acute and chronic diffuse glomerular nephritis. It did not delay the recovery of patients with acute diffuse glomerular nephritis, who showed a gradual improvement in renal efficiency.

Impairment of renal function was increased temporarily by the ingestion of alcohol by patients with arteriosclerotic nephritis (nephrosclerosis).

Typical detailed studies of cases of acute diffuse glomerular nephritis, chronic diffuse glomerular nephritis and arteriosclerotic nephritis are given in tables 2, 3 and 4. Table 2 demonstrates that the ingestion of 150 cc. of rye whisky (equivalent to 300 cc. of a 25 per cent solution of pure ethyl alcohol) does not impair the gradual improvement in the Addis count of a patient

with acute diffuse glomerular nephritis. Table 3 shows that the ingestion of 150 cc. of a 25 per cent solution of alcohol by a patient with chronic diffuse glomerular nephritis is not followed by any deleterious effect on renal function; in fact, the functional capacity of the kidneys shows some improvement, as indicated by a decrease in the urea nitrogen content of the blood, by a diminution in the urea ratio and by an increase in the urea clearance. Table 4 demonstrates a marked increase in the number of red blood cells in the urine and a decrease in the urea clearance for a patient with arteriosclerotic nephritis after the ingestion of 100 cc. of rye whisky (equivalent to 200 cc. of a 25 per cent solution of alcohol). No significant effect was observed after the first and smaller dose, 50 cc. of rye whisky.

COMMENT

These studies do not answer the question as to the part played by alcohol in the causation of Bright's disease. However, it is significant that acute and chronic diffuse glomerular nephritis are not aggravated by alcohol and whisky in the doses given, whereas a transient deleterious effect is observed frequently on arteriosclerotic nephritis.

The following hypothetic considerations are offered in an attempt to explain these observations: Since the taking of alcohol in moderate doses is followed by a peripheral vasodilatation (as indicated by the feeling of warmth and flushing of the skin), a redistribution of blood after its ingestion may diminish the flow of blood through the kidneys. In cases of arteriosclerotic nephritis, diverting blood from the kidney to the skin may aggravate the renal lesion, since in such cases the flow of blood is already impaired by vascular sclerosis. With glomerular lesions, however, particularly acute diffuse glomerular nephritis, such a redistribution of blood would tend to reduce congestion in the glomeruli and the taking of alcohol in moderate doses may even be desirable or at least not be followed by undesirable effects.

The diuresis frequently noted after the ingestion of alcohol or of alcoholic beverages is of clinical importance. The diuretic effect is considered to be due to the large amount of fluid usually imbibed with it or to the presence of other substances (as in the distillates), especially volatile oils, and not to a specific action of the alcohol. In 1910 Mendel and Hilditch [25] gave two young men 96 cc. of 95 per cent alcohol daily in six doses of 16 cc. each and obtained no diuretic response. Their work has been quoted widely, even in modern textbooks,[26] to indicate that alcohol per se is not a diuretic agent. This contention, however, has been refuted by an appreciable amount of work carried out since 1910.[27] The present studies show that alcohol increases the output of urine, even in the presence of decreased functional capacity of the kidneys.

CONCLUSIONS

Alcohol or whisky in moderate doses rarely augments the proteinuria of patients with Bright's disease. Moderate diuresis may be induced even in the presence of marked impairment of renal function. Alcohol or whisky has no deleterious effect on the kidneys of normal subjects, nor does it aggravate the renal lesion in patients with acute or chronic diffuse glomerular nephritis. In patients with arteriosclerotic nephritis (nephrosclerosis) the ingestion of alcohol or of whisky is followed frequently by a transient increase in the number of red and white blood cells and casts excreted in the urine and by a temporary diminution in renal function.

APPENDICITIS IN ADULTS

REVIEW OF 2,000 CONSECUTIVE CASES, WITH COMMENTS ON THE RISING MORTALITY OF THE ACUTE SUPPURATIVE TYPE

F. R. KELLY, M.D.
AND
R. M. WATKINS, M.D.
CLEVELAND

In 1931 one of us [1] reviewed the records of 1,000 consecutive cases of acute suppurative, acute simple and chronic appendicitis in adults as they occurred in the files of Woman's Hospital. This nomenclature was used in accordance with the pathologic reports on the appendixes sent to the hospital laboratory.

In this paper we present a review of the next thousand cases in adults and compare this series with the former one. We were anxious to learn whether there were wide variations in the statistics and to try to explain them if possible (table 1).

It may be seen that there are no great variations in the data for the two series except for the marked increase in the death rate of acute suppurative appendicitis; this rate has increased from 9 per cent in the first series to 23 per cent in the second. Quain and Waldschmidt [2] reported a mortality rate of 10 per cent in a series of 1,000 cases between 1919 and 1927 and found, as we did, that there was a sharp increase in the mortality to 18.8 per cent in their second series of 1,000 cases during the depression years.

Forty-five of 193 patients in the second group with acute suppurative appendicitis died; the causes are shown in table 2.

In the earlier series the proportions were about the same. These data agree with those of McKenna [3] and Davis and his associates.[4] Davis found among fifty-five deaths forty-one due to immediate and fourteen to remote causes. In McKenna's series fifty-nine were due to immediate and nineteen to remote causes.

WHY HAS THIS MORTALITY INCREASED?

The increase in mortality can be explained in three words: delay in operation. We have in mind three causes for this delay:

A. *Changed Economic Conditions.*—The first thousand cases occurred from about 1925 to 1930, when the nation was in a prosperous state economically. The second series of 1,000 occurred from 1931 to 1936, when conditions were entirely different. The records show that in the early series the patients were ill for 3.8 days before operation and in the later series for 4.9 days. This means that during these depression years patients delayed operation 29 per cent longer than in better times. This surely increased the mortality rate. Quain and Waldschmidt [2] found that the average time between onset of illness and operation was more than twenty-four hours longer in the second series than in the first and attributed their increase in mortality in part to this delay.

B. *Home Treatment, Especially with Laxatives.*—This subject may be a corollary of the previous one, because the increase of the use of home measures probably is a mirror of the economic state During the delay in reaching surgical aid the patient is using various medicines suggested by those about him, and among them, unfortunately, are laxatives. We have gleaned from the records the facts that in the 1925-1930 series 24 per cent of the patients reported the taking of laxatives for their attack, whereas during the later series 42 per cent reported having done so. We feel that the increase of laxative taking has been partly responsible for the increase in mortality. Of the patients who died of what we term immediate causes twenty-one, or 67 per cent, reported taking laxatives.

We believe that credit should go to Bower [5] of Philadelphia for actively campaigning for education of the public in this regard. He compiled the results obtained in several hospitals and found that of 306 patients who died of acute suppurative appendicitis 147, nearly half, had taken laxatives. In another series he reported that 91.6 per cent of 214 patients who died of acute diffuse peritonitis had taken them. Blackburn [6] reported a series of cases in which one of sixteen patients who used a purgative died, whereas of those who had not used laxatives only one of 109 died

In our series we tried to estimate from the history the length of time from the rupture of the appendix until the operation.

Twenty-eight of our 190 patients with acute suppurative appendicitis in the second series were operated on less than twenty-four hours after the rupture; only 3.5 per cent died. Of eighty-six who were operated on forty-eight or more hours after rupture, 32 per cent died.

Giertz [7] of Stockholm found about the same proportions. His figures are 3.5 per cent mortality if the operation was done within forty-eight hours of the onset of peritonitis and 23 per cent if more than forty-eight hours had intervened.

C. *Delay in Operation Because of Urinary Abnormality.*—In going over the records we were not surprised to find the usual variations in leukocyte counts, temperature and pulse readings, but we did not expect to find so many laboratory reports of red blood cells in the urine. In the first series only those cases in which a considerable number of red blood cells were reported by the laboratory were noted in the statistics, whereas in the second series any mention of red blood cells, even though of only an occasional cell, was noted, which may account in part for the great variance

Hematuria Associated with Acute Appendicitis: It has often been said jocularly that every patient with chronic genito-urinary symptoms has a McBurney scar. Genito-urinary symptoms and signs may often obscure the picture of acute appendicitis and thereby delay operation and increase the mortality rate Hematuria is the most important offender among the urinary abnormalities and deserves discussion.

Collins [8] reported 1,402 consecutive cases of emergency appendectomy. Hematuria was found in 88 per cent of these. He stated that exclusion of other causes of the hematuria delayed operation an average of four hours and increased mortality from 4.7 to 6.2 per cent In our series, with acute and suppurative appendicitis

hematuria occurred in 7.9 per cent, a not infrequent occurrence. The incidence of hematuria with acute retrocecal appendicitis is great. Collins found it present in 83.9 per cent of his cases and we found it in 62 per cent of ours. This high incidence is due to the close proximity of the acutely inflamed organ to the ureter, causing secondary ureteritis.

Pulmonary embolus	1

When the surgeon is confronted with such a condition in a patient suspected of having acute appendicitis, what is he to do? Delay may be dangerous, yet he does not wish to remove a normal appendix. Certainly a quick and reasonably thorough investigation of the urinary tract should be made before any operative procedure is undertaken. Catheterized specimens should be examined to exclude any possible extraneous sources of contamination. If erythrocytes are still present, a plain roentgenogram of the urinary tract is the next step. If this reveals no calculi, he should then take stock of the situation. Often this amount of information, admittedly not thorough, but with the other laboratory data and the clinical picture, is enough to warrant an exploratory laparotomy. There are occasions, however, when the clinical picture is still indefinite, despite this additional information, and the next step is intravenous pyelographic study, to visualize the urinary tract and further to rule out any calculi, ureteral strictures, torsion or tumors. A final step, if time and conditions permit, is cystoscopic study and catheterization of the ureters.

Let us again call attention to the frequency of hematuria in cases of acute appendicitis, particularly if the appendix is retrocecal. We do not believe that a surgeon should relax his vigil when faced with hematuria and allow time to supply the answer. Appendicitis is exacting too high a mortality already. It is the surgeon's duty to conduct a prompt investigation of the urinary tract as thorough as the condition of the patient allows.

Experience of Others.—We do not feel proud of our mortality statistics, but we are not so chagrined when we compare them with others (table 3).

TREATMENT OF DIFFUSE APPENDICAL PERITONITIS

We do not feel it necessary or suitable in this paper to discuss all the details of treatment of appendicitis in general; instead we wish to convey the ideas of ourselves and others with regard to two features of the treatment of diffuse or general peritonitis secondary to acute suppurative appendicitis with rupture. No one form of treatment of this condition is practiced by all surgeons. From the literature we have found that a number of representative surgeons favor deferring any operation in a certain type of diffuse appendical peritonitis. Only a few cases fit into this category, but they are plentiful enough so that the matter should be presented.

A. *Deferred Operation.*—Coller and Potter [9] have expressed the belief that operation should be postponed until a propitious time in all cases in which the appendix has ruptured and peritonitis has developed to the extent of being generalized. If they first see the patient two or three days after peritonitis has begun and it has become diffuse, they are inclined, if the patient's condition will allow, to wait from six to eight weeks and to secure as great localization as possible before operating. Guerry [10] has stated the opinion that this plan applies more to late than to early diffuse peritonitis.

If this plan is followed, the well known 1892 Ochsner[11] method of treatment is employed. This is directed toward allowing the entire gastrointestinal tract as near complete rest as possible, plus the use of fluids parenterally administered, liberal amounts of opiates, Fowler's position and dry heat to the abdomen.

Again let us emphasize that comparatively few cases arise in which the question of deferred operation occurs.

Reid and his associates [12] have recommended and practiced the Ochsner treatment in certain cases, in the hope of lowering the mortality rate in this small group.

Guerry [10] compared two series. In the first, with immediate operation, the mortality rate was 10 per cent; in the second, in which operation was postponed, the rate was 1.4 per cent.

Coller and Potter [9] reported a series in which operation was deferred with a death rate of 9.4 per cent.

B. *Immediate Operation.*—Operation should not be deferred in cases of (1) acute simple appendicitis, (2) early suppurative appendicitis before generalized peritonitis has developed, (3) suppurative appendicitis with localized abscess, (4) general peritonitis associated with pregnancy and (5) doubtful diagnosis.

C. *Drainage vs. Nondrainage in Appendical Peritonitis.*—We recognize the fact that the policy of deferring operation applies to only a few cases of suppurative appendicitis and that the large majority of

2,000 averaged	Acute suppurative	16.4

patients should be operated on without delay. The subject we wish to discuss here is when drainage should be used and when not used.

Drainage should be used in all cases of walled-off abscess formation. If the appendix is readily accessible it should be removed; if not, it should be left alone to avoid manipulation with resultant breaking of pro-

tective adhesions and spreading of infection; also, if the appendix is not removed, drainage should be used even though general peritonitis is present. However, if the appendix is removed, and even though general peritonitis is present with free fluid throughout the abdomen, and that fluid frank pus, drainage should not be employed. The objections to drainage in this condition are:

1. It is impossible to drain the entire abdominal cavity.
2. The material forming the drains stimulates the formation of additional adhesions between the abdominal organs and the peritoneal surfaces and increases the danger of intestinal obstruction and mechanical ileus.
3. A wide and weakened incision with its accompanying direct hernia is a frequent complication.
4. These developments prolong hospital stay and expense.
5. These factors definitely increase the mortality rate according to most surgeons.

In this connection Cafritz[13] quoted Marchini as reporting 285 cases in which drainage was used and 158 in which it was not. In the former group the death rate was 14 per cent and in the latter 5.6 per cent. Krasnoselskiy[14] reported 1,944 cases, with 17 per cent mortality in the drainage group and 1.5 per cent in the nondrainage group. In our own group only nineteen patients were treated by closure without drainage; there was but one death, and that from postoperative pneumonia. The other 171 patients had drainage, and forty-four died, a rate of 25.7 per cent. These figures seem significant, even though our series is small and not divided according to the presence or absence of localized abscess.

REMEDIES

A. *Education of the Public.*—It is probably too soon to estimate the results of the Philadelphia campaign, but it seems to us to be the one most efficient means of getting the public to cooperate by seeking early medical attention for abdominal pain. If economic conditions improve, this delay on the patient's part will be lessened, but in the meantime persons should be told to pocket their pride and seek medical aid regardless of their circumstances if they have pain in the abdomen. For this educational measure the great publicity mediums of newspapers, magazines, radios, public speeches and placards can well be used, as they are being employed now in the campaigns against cancer and syphilis. Especial attention must be placed on the danger of taking purgatives in the presence of abdominal pain.

B. *Education of the Physician.*—It seems trite to state that the physician should be told that with few exceptions appendicitis is a surgical disease. Rarely the patient has another disease that precludes operation, but modern surgery and modern methods of anesthesia make the operation in cases of early involvement so simple that a patient with advanced degenerative disease or serious infection can tolerate it with reasonable safety.

Early operation is another important factor. The mortality rate of chronic and uncomplicated acute appendicitis is so low that it is well worthwhile to remove the organ promptly and avoid the dangers of delay.

SUMMARY

We have analyzed another thousand cases of chronic, acute simple and acute suppurative appendicitis in order of occurrence at Woman's Hospital and have found no great variations from the first thousand cases except a sharp increase in the mortality rate (9 per cent to 23 per cent) for the acute suppurative type.

We believe the increased mortality to be due to delay in operation and that in turn to (*a*) economic causes, (*b*) the tendency to use home remedies, including purgatives, for a protracted time and (*c*) complicating factors in diagnosis causing delay in operation.

In a few cases of suppurative appendicitis the operation should be deferred. In the greater number, however, surgical measures should be taken at once. A decrease in the mortality rate can be obtained by education of the public to avoid delay in seeking medical attention and by education of the physician to take prompt action when indicated.

BOWEL ANTIGEN

IV. THE CLINICAL USE OF A NEW METHOD TO DETERMINE THE PRESENCE OF THE VIRUS OF LYMPHOGRANULOMA VENEREUM IN THE DIFFERENTIAL DIAGNOSIS OF INTESTINAL INVOLVEMENTS

MOSES PAULSON, M.D.

Associate in Medicine, Johns Hopkins University Medical School, Physician (Consultant in Digestive Diseases), Diagnostic Clinic, and Assistant Visiting Physician, Johns Hopkins Hospital

BALTIMORE

I. EXPERIMENTAL AND CLINICAL BACKGROUND FOR THE CLINICAL USE OF BOWEL ANTIGEN[1]

Involvements of the intestine of known cause are those due to neoplasms, bacterial and parasitic infections, bacterial toxins associated with food poisoning, vitamin deficiencies and the excretion of poisonous chemicals A decade ago lymphogranuloma venereum, now generally regarded as due to a virus, was associated with rectal stricture because of the frequent concomitant occurrence of the latter condition with a positive Frei reaction. More recently some authors have assumed that a positive Frei reaction associated with intestinal diseases indistinguishable pathologically and clinically from bowel disorders of diverse or unknown origin is indicative that this virus is the cause. This is true in many instances, but given a specific case it is not possible merely by means of the Frei reaction to establish such a connection. Even the clinical aspects and the pathologic picture of lymphogranuloma venereum are not pathognomonic.

The most that can be said is that a positive Frei reaction in association with a bowel disorder can suggest the possibility of viral origin. A positive Frei reaction is an allergic intracutaneous response to inactivated bubo pus containing the virus of lymphogranuloma venereum. It merely establishes the fact that the

From the Gastro-Enterological Section and Laboratories of the Medical Clinic of the Johns Hopkins University and Hospital

Read at the third annual convention of the National Society for the Advancement of Gastroenterology, New York, June 2, 1938

1. The term antigen strictly speaking is limited to substances known to engender antibodies when injected into the animal organism "Bowel antigens" may or may not produce them; their composition is not completely known, but this term has been used because all bowel antigens are manipulated in much the same manner as other true antigens. Bowel antigen and associated terms have also been employed to avoid confusion by readily distinguishing the bowel antigen and its response from the Frei antigen and its reaction.

reacting subject is or has been infected at some time in his life with this virus. The Frei reaction will be positive even though this viral infection has ended as a simple bubo. The viral infection, active, inactive or terminated, resulting in a positive Frei reaction, may bear no relation to the intestinal involvement. A positive Frei reaction does not establish the presence of the virus in any involved tissue except in the bubo. Any other deduction is simply inferential attended by all the limitations of such reasoning. Indeed, not all patients infected with the virus of lymphogranuloma venereum, with or without concomitant intestinal disturbances, give positive Frei reactions.

Bowel antigen—a new, practical diagnostic aid—appears to offer a more direct and specific method of determining the presence of the virus in intestinal tissue and discharge, both *ante* and *post mortem*. Inactivated blood, mucus, pus and intestinal contents grossly free from feces compose what is known as a bowel *discharge antigen*. *Bowel tissue free from fecal contamination*, preferably fresh and unfixed, macerated and inactivated, makes up bowel tissue antigen. The preparation of the patient and the technic for the securing of material for use as bowel antigens, the preparation of the antigens, their intracutaneous inoculations into a minimum of three subjects known to have a positive reaction to the Frei antigen and into at least three controls, neither group manifesting any systemic disorder or organic gastrointestinal disease, and the interpretations of the reactions have been discussed in detail elsewhere.[2]

A positive reaction to bowel antigen parallels the positive response to Frei antigen inoculated simultaneously for purposes of comparison.

A positive bowel antigen (one producing positive reactions) indicates the presence of the virus in the tissue or in the discharge of the patient from whom the material was secured. A negative bowel tissue antigen prepared from actively involved tissue is more significant than a negative bowel discharge antigen, because in the latter the antigenic material may be too greatly diluted or lost as a result of dysentery. Neither type of negative antigen determines the absence of the virus as conclusively as a positive antigen indicates its presence.

The conclusion that a positive bowel antigen indicates the presence of the virus in the tissue or discharge of the patient from whom it was secured is based on analogy and experimental evidence, which also indicates its pathogenic significance.

A. *Analogy.*—A positive bowel antigen like the Frei antigen will produce positive responses in persons known to have been infected with the virus of lymphogranuloma venereum. The type of intradermal reaction, unlike any produced by known bacteria, toxins, foreign proteins or other allergens, and their interpretations are identical. Strains of both Frei and bowel antigens vary similarly in their antigenic qualities. Control subjects, free from systemic or organic gastrointestinal disease, give negative reactions to both types of antigens. Bowel antigens produce a negligible number of false positive reactions. This is striking when one considers their present crudity.

The only reference encountered to work of a similar nature is that of Nicolas, Favre, Lebeuf and Charpy,[3] who secured an antigen from the pus exuding from a fistula of a person with anorectal elephantiasis and a positive Frei reaction. In three persons with positive Frei reactions this antigen produced a positive response. No control work of any nature or details of technic and of interpretations are reported. A similar effort with material from a similar source was reported by Wien and Perlstein. The same criticism can be offered of their work.

B. *Experimental Evidence.*—1. Findlay[4] summarized the data to 1936 as follows:

> Ravaut, Levaditi, Lambling and Cachera (1932), and Laederich, Levaditi, Mamou and Beauchesne (1932), by an ingenious technic, isolated from inflamed rectal tissue [vegetation secured by biopsy] a virus which agreed in every way with the viruses isolated from cases of lymphogranuloma inguinale by Hellerström and Wassén (1930), Levaditi et al. (1931) and Findlay (1932). A similar virus isolated by Mocquot, Levaditi and Reinié (1935), from an inflammatory condition [vegetation secured by biopsy] of the colon, proved of considerable interest, for with this strain Levaditi, Mollaret and Reinié (1935) produced the histological changes characteristic of lymphogranuloma inguinale in the rectum of chimpanzees by direct inoculation into the mucosa, while in human volunteers they reproduced the primary penile sore with involvement of the inguinal glands—the lesions typical of lymphogranuloma inguinale. [The human subjects were negative to the Frei antigen prior to the inoculation and positive to it subsequently.] A green monkey Cercopithecus calli thrix was inoculated (Findlay, 1935) immediately anterior to the rectum, with a virus isolated in this country from the enlarged inguinal glands of a patient with genital lymphogranuloma inguinale and passed through mouse brains. Ten days after inoculation the monkey was killed and a swelling about the size of a hazelnut was found at the site of injection, while the mesenteric glands were swollen. From the inflamed tissues involving the rectal wall—which histologically were characteristic of lymphogranuloma inguinale—and from the mesenteric lymph nodes there was recovered a virus that produced meningitis in mice and resembled in all respects the virus of lymphogranuloma inguinale. There is thus little doubt that the same virus is responsible both for the genital lesions of lymphogranuloma inguinale and for the rectal lesions associated with certain cases of stricture.

2. A male dog was parenterally inoculated by me[5] with uninactivated bowel discharge from a patient from whom a positive bowel discharge antigen had been obtained. The dog's intradermal reactions to two active human Frei antigens were positive at fourteen days. Prior to administration of bowel discharge the animal gave a negative reaction to three active Frei antigens, one of which produced one of the two positive reactions referred to. A control antigen consisting of inactivated bubo pus of nonspecific origin from several human sources produced no reaction. This, it is believed, tends to establish further that the virus is present in material from which a positive bowel antigen is made, and the intradermal response is brought about by the virus or an associated product.

A stricture or vegetations with or without colitis have not been produced with this virus experimentally. The evidence to date seems to establish that the virus is present in vegetations and strictures associated with

rectal involvements in many persons with positive Frei reactions. It also shows that it is present in the bowel discharge as well as in bowel tissue, with or without stricture, elephantiasis or fistula. The evidence points out that this agent is identical with the virus encountered in the genital phase of lymphogranuloma venereum. The ability of the virus obtained from rectal vegetations to reproduce genital lymphogranuloma venereum in man, and inguinal adenopathy and meningoencephalitis in lower animals establishes its pathogenic propensities. In view of this and much striking clinical evidence, it seems reasonably safe to assume at this time that the presence of the virus in the intestine as indicated by a positive bowel antigen is of pathogenic significance. Bowel antigen seems now to have made possible the practical clinical application of the experimental data adduced heretofore.

II. THE APPLICATION AND SIGNIFICANCE OF BOWEL ANTIGEN IN CLINICAL PRACTICE

A. *Rectal Stricture.*—The colonic involvement commonly recognized as due to the virus of lymphogranuloma venereum is the advanced stage of the disease. It appears as a rectal stricture in a person with a positive Frei reaction, frequently with fistulas and anal and genital elephantiasis, often associated with ulceration and polyposis. This relatively easily recognized clinical picture is now no longer a diagnostic problem. The use of bowel antigen here would not seem essential; however, its use may be desirable for confirmation.

This clinical state, even in the absence of a positive Frei reaction, has been considered as due to this virus. The discrepancy is explained on the basis of anergy. It has been estimated by Frei that about 10 per cent of such cases manifest anergy. The actual extent of this phenomenon is not known, since not all rectal strictures and not all the so-called typical clinical states referred to are due to the virus of lymphogranuloma venereum. Also, the extent of anergy in the absence of this advanced stage or in states indistinguishable from those brought about by other agents has yet to be determined. At this writing the only direct method of establishing anergy in either of these typical or less typical conditions rests on the procuring of a positive bowel antigen.

The following cases of the typical or advanced bowel states usually associated with lymphogranuloma venereum but with negative Frei reactions are illustrative of the use and significance of bowel antigen:

CASE 1.—A white man, an American, aged 59, seen in 1937 because of rectal stricture and ulcerative colitis, in 1922 had had inguinal adenopathy on the right which was drained. In 1927 a stricture of the lower part of the rectum was discovered. In 1937, when the Frei antigen was first used on him, he gave a negative reaction to five active human strains.

Was the bubo due to the virus of lymphogranuloma venereum? Were the colitis and stricture, occurring five years after his bubo, due to this virus? Were they unrelated? Was this case one of anergy?

His bowel discharge antigen produced eight positive and five negative responses in thirteen patients with positive Frei reactions and twenty-three negative reactions in twenty-three patients with negative Frei reactions. Here bowel antigen indicated clearly that the problem—one of anergy—was associated with the virus of lymphogranuloma venereum.

CASE 2.—A white woman aged 48, seen in consultation by me in the diagnostic clinic of the Johns Hopkins Hospital for rectal pain and bleeding, five years previously had undergone excision of the left kidney presumably for relief of lithiasis. A sinus exuding pus persisted in the postoperative wound. The perineum and labia majora were "indurated and stony hard"; the vagina did not permit the insertion of a finger. The anus, through which only the tip of the small finger could be inserted, was strictured and fissured and discharged pus; a rectoscope with a two-eighths inch diameter could not be passed for more than 2 or 3 cm. The anogenital tissues were hypertrophied.

Both the gynecologist and I at first thought the problem to be one of lymphogranuloma venereum, for the clinical picture was highly suggestive. When the patient failed to react to five different strains of active human Frei antigen, the following questions arose: Was the case one of anergy? The sinus persisting after nephrectomy suggested tuberculosis. The Wassermann reaction of the blood was negative, and the patient had had no antisyphilitic therapy. Was the condition malignant? A biopsy specimen of anal tissue and a bowel discharge antigen were obtained. Injection into guinea-pigs of material from the nephrectomy wound produced no sign of tuberculosis. The bowel antigen gave negative results and the pathologist reported squamous cell carcinoma.

This case teaches that even the advanced clinical state said to be typical of lymphogranuloma venereum may be a manifestation of other conditions. As lymphogranuloma venereum is increasingly emphasized, there is danger of overlooking or forgetting other etiologic factors in clinically similar situations. Lymphogranuloma venereum, which in this instance at first seemed unmistakable, could not be established. While it is still possible that the virus may have borne some relation to this problem, experience with bowel antigen appears to make this possibility more remote.

Further Comment: The significance of bowel antigen is emphasized when these two illustrative cases and their implications are considered together. Both patients were white, one a man and the other a woman; both presented strictures; the man also had ulcerative colitis above the stricture; both failed to respond to multiple active human Frei antigens; both had the typical clinical picture of lymphogranuloma venereum, the man giving a history of the genital phase, the woman —as is often the case—having no knowledge of the earlier phases. Only by inference, by virtue of the so-called typical clinical picture, could it be assumed that the infection in each case was due to the virus of lymphogranuloma venereum. Even this inference was not particularly strong when the patients failed to respond to the Frei antigen. In the man, the presence of the virus was determined by obtaining a positive bowel antigen, not an inferential but a direct diagnostic procedure. The woman's antigen was negative and the problem was solved by the finding of squamous cell carcinoma. Bowel antigen provides a direct indication of the presence of intestinal venereal lymphogranuloma. It reduces the necessity for inference. What inference may lead to is exemplified specifically by the fact that for years every stricture of the rectum was regarded as due to syphilis because some persons with strictures had positive Wassermann reactions.

B. *Other Intestinal Conditions.*—Bowel antigen is of import in the differential diagnosis of intestinal disorders, particularly when the clinical manifestations appear to be at variance with the so-called typical clinical distal state of intestinal lymphogranuloma venereum already referred to. It is with such problems, now not generally recognized as possibly associated

with this virus, that bowel antigen should find its greatest usefulness, as indicated by the following cases:

1. Dysentery:

CASE 3.—*Ulcerative colitis with a negative Frei reaction.* A Negress aged 24, examined Dec. 22, 1937, because of rectal pain and bleeding on defecation, had noted a "lump in the right groin" on November 18. Gynecologic examination revealed bilateral inguinal adenopathy. There was no rectovaginal fistula or anogenital elephantiasis. Vaginal smears showed no gonococci. She failed to react to chancroidal vaccine and to multiple human Frei antigens as late as May 1938, and numerous attempts to aspirate pus from the buboes were unsuccessful. Rectosigmoidoscopic study revealed progressively severe colitis without mass or stricture, exuding blood and mucopus and extending from the anorectal margin 12 or 15 cm., the brunt of the involvement being within the first 5 cm. Bacteriologic, parasitologic, serologic and roentgenologic study gave no significant information.

My inability to ascribe this patient's inguinal adenopathy to lymphogranuloma venereum, her consistent failure to react to multiple human Frei antigens, the absence of an intestinal or genital picture suggestive of lymphogranuloma venereum and the lack of evidence suggesting any other etiologic agent resulted in the condition being designated nonspecific ulcerative colitis.

However, the bowel antigen obtained in this case gave six positive reactions in eleven patients with positive Frei reactions and no reactions in ten patients with negative Frei reactions. A positive discharge antigen from the generative tract was also secured. This will be the subject of a forthcoming publication.

Thus it was demonstrated with bowel antigen that this apparent nonspecific ulcerative colitis was actually associated with the virus of lymphogranuloma venereum. Anergy, in this case not clinically typical of lymphogranuloma venereum, could have been discovered only by this procedure.

Anergy, together with the failure to recognize the possible association of this virus with intestinal conditions different in appearance from those described as "typical," results in a reported frequency of viral infection lower than the probable true incidence. Bowel antigen should aid in such determination.

CASE 4.—*Ulcerative colitis with a positive Frei reaction.* A Negro aged 19 with a positive Frei reaction had typical, apparently indeterminate ulcerative colitis without stricture three years after a bubo involvement. Was the intestinal disorder unrelated to his venereal disease? The answer rests on the fact that ten of eleven patients with positive Frei reactions gave positive reactions to his bowel discharge antigen; eighteen with negative Frei reactions gave negative reactions to it; there were no false positive reactions.

Further Comment: What might be expected from the use of bowel antigen is again emphasized when the two foregoing cases are considered together. Both patients had had buboes; the man gave positive Frei reactions; the woman failed repeatedly to respond to multiple active strains of human Frei antigen. Both had apparent typical nonspecific ulcerative colitis. If inference were to establish the virus of lymphogranuloma venereum as the cause of ulcerative colitis because of a positive Frei reaction and a previous bubo in the case of the man, was inference also to result in the contrary conclusion for the woman when there was a bubo which might have been due to any one of several agents and no response to the Frei antigen? A positive bowel antigen from each solved the problem not by inference but by directly indicating the presence of the virus of lymphogranuloma venereum in the involved intestine. Clinically such a result might well be regarded as of etiologic significance.

Bowel antigen makes possible the detection of intestinal venereal lymphogranuloma before the clinical picture becomes advanced and typical, thus facilitating early therapy in the hope of avoiding the later, frequently incurable manifestations. The incidence of venereal lymphogranuloma in cases of so-called typical ulcerative colitis is as yet not known. Bowel antigen offers the only practical available means for its determination.

2. Inflammation of the Terminal Portion of the Ileum, Cecum and Ascending Colon with Positive Frei Reaction:

CASE 5.—A Negro aged 27 came to the hospital Oct. 28, 1937, because of a painful lump to the right of the umbilicus, which he had noted for the first time two days prior to admission. Two weeks earlier he experienced a generalized dull ache in the right upper part of the abdomen, which apparently had come on during the course of an evening and persisted until admission. There was daily defecation. No change in the consistency of the stools, no mucus, pus or bright red blood in the feces and no melena, nausea, vomiting, chills or urinary symptoms were encountered. The temperature was 100.2 F., the pulse rate 78, the respiratory rate 18, and the blood pressure 112/80. A movable tender mass, not attached to the liver, 2 inches to the right of the umbilicus was noted. Rectal examination including examination of the prostate gave negative results. The urine was normal, and the white blood cell count was 12,000. The tentative diagnosis was of "inflamed appendix causing inflammation and matting of a loop of the intestine, or a cecal mass either tuberculous or malignant."

In 1934 he was seen during intense abdominal pain and in mild shock. A perforated duodenal ulcer was closed. In 1930 he had had gonorrhea.

At operation it was difficult to decide whether the condition of the resected cecum, ascending colon and terminal portion of the ileum was inflammatory or malignant. The impression of the pathologist, who found a foreign body ("a piece of wood or a piece of peach or prune pit") embedded in the mass, was that the process was active nonspecific inflammation. It appeared not unlike that described for either regional ileitis or lymphogranuloma venereum. The results of subsequent efforts to clarify its causation with respect to tuberculosis and infection by the typhoid-paratyphoid-dysentery group of organisms were negative. The patient did not respond to Ducrey bacillus antigen. He gave a positive Frei reaction, but he stated that he had had no bubo involvement and there was no inguinal scarring.

The clinical manifestations and gross and microscopic study of tissue and other investigations offered no aid in ascertaining the cause. The positive Frei reaction merely suggested a possible association between the virus of lymphogranuloma venereum and the lesion. The bowel tissue antigen was negative in six cases of positive and in six of negative Frei reactions.

If the virus was the cause of such an active process, it was reasonable to expect its presence in the involved tissue and hence its manifestation by this method because of the relative ease with which I have secured positive tissue antigens from the rectum and sigmoid flexure. At any rate, this negative antigen casts further doubt on the inference that because the Frei test gave a positive result the virus of lymphogranuloma venereum was the causative agent.

Bowel tissue antigen and bowel discharge antigen should be employed in all cases of obscure intestinal disorders. When there is a positive Frei reaction, bowel antigen offers the only practical method to determine the connection between such a reaction and the cause of the lesion. Even when the Frei test is negative, the virus may be present in the lesion (anergy). Bowel antigen is the only available practical means by which the cause in these cases can be discovered.

III. SUMMARY

The evidence to date—experimental and clinical—supports the view that the virus of lymphogranuloma venereum in intestinal discharge or tissue is of pathogenic significance. The only direct clinical method now available to determine the presence of the virus in such sources is in the use of bowel antigen. When bowel antigen is positive it indicates the virus of lymphogranuloma venereum in the bowel tissue or discharge from which it is obtained.

Bowel antigen is important because:

1. The clinical picture is not pathognomonic. The so-called typical state of intestinal lymphogranuloma venereum is not always caused by this virus.

2. Some cases clinically indistinguishable from nonspecific ulcerative proctitis or colitis are found associated with the virus of lymphogranuloma venereum by means of bowel antigen.

3. The pathologic picture—grossly and histologically—is not pathognomonic. Bowel antigen may aid in differential diagnosis ante and post mortem.

4. The Frei antigen alone in differential diagnosis is inadequate because:

(*a*) The patient may give no reaction to Frei antigen, and bowel antigen may indicate virus presence (anergy).

(*b*) A positive Frei reaction may be produced by an antedated or healed virus infection or one unrelated to the bowel disturbance.

Medical Arts Building.

ALLERGIC MANIFESTATIONS WITH INJECTION TREATMENT OF VARICOSE VEINS

DEATH FOLLOWING AN INJECTION OF MONOETHANOLAMINE OLEATE (MONOLATE)

HAROLD J. SHELLEY, M.D.
Assistant Attending Surgeon and Chief of Surgical Clinic, St. Luke's Hospital
NEW YORK

Deaths resulting from injections given in the treatment of varicose veins fortunately have been very rare. Reports of death due to emboli have practically disappeared from the medical literature since the use of coagulant solutions has been given up and since the realization has become general that the patients during the course of their treatment must be kept ambulatory.

However, the hazard from the phenomena of allergy has not been eliminated and remains a real danger which must be borne in mind continuously by surgeons using injections in the treatment of varicose veins.

REACTIONS ACCORDING TO THE SOLUTION USED

The various sodium chloride or sugar solutions are not entirely free from this danger, as nitrogenous impurities may be contained in them. The resultant reactions of course should occur but rarely and be minor. That they do occur is borne out by Probestein's [1] report of a nitritoid reaction after the injection of a solution of invert sugar. In 1938 a case [2] was described in which dermatitis of the involved leg with a slight dermatitis on both arms and the sacral regi developed after the second injection of the solution.

In addition to the typical evidences of salicylis which frequently follow the use of sodium salicyla for injecting varicose veins, Meisen [3] has noted urticar following its use.

Quinine, when used as a solution of quinine ar urethane, not infrequently causes urticaria or derm titis, which may even develop into severe weepir eczema. Immediately after the injection of this sol tion into a patient sensitive to quinine a generaliz urticaria may develop, associated with asthma so seve that the patient is unable to breathe until given a lar dose of epinephrine hydrochloride. I know of no ca in which this has been fatal but have never seen a ca in which epinephrine was not given immediately.

Sodium morrhuate causes a variety of allergic rea tions. This fact is not surprising, in that in the prep ration of this solution it is impossible to remove a nitrogenous materials contained in the cod liver oi In 1932 Ritchie [4] called attention to these reactions an described the following three types:

1. Erythematous or urticarial manifestations of th skin.

2. Gastrointestinal disturbances with abdominal pai and diarrhea appearing shortly after injection.

3. Collapse with cyanosis, pallor, low blood pressur and temporary loss of consciousness.

To cases of the first type I would add those in whic in the course of treatment by injections of the sodium morrhuate solution an itching, thickened, red are appears in the skin over the veins injected some tim previously. If the injections of this solution are stoppe this rash disappears, but if the treatment is continue the condition spreads, soon becoming a fairly well gen eralized weeping eczema.

The second type described by Ritchie [4] is probably only a mild form of the third, which is of course a severe nitritoid reaction and, when sufficiently severe, may cause death. Levi [5] in 1938 called attention to the fact that deaths have followed the injection of sodium morrhuate. That death occurs oftener than the medical literature would indicate is evidenced by the fact that one physician from the medical examiner's office in New York City, as he has advised me, has seen three such deaths in the course of his duties, none of which have been reported in any medical magazine. These reactions, as is typical of the greater number of the severe reactions following the injection of sodium morrhuate, occurred with the first or second injection following at an interval after a previous series of injections of the same solution. Lewis [6] and Zimmermann [7] have described this type of sensitization phenomenon, but in patients who recovered from the resulting reactions.

On a number of occasions I have seen a similar but milder reaction following the patient's first injection of sodium morrhuate solution. It is impossible, of course, to prove that these less severe manifestations may not have been psychic.

That cessation of treatment for a period is not necessary to the development of this allergic state is testified to by the case reported by Dale,[8] in which a severe nitritoid reaction followed the thirteenth in a series of injections spaced at regular intervals. Hatcher and Long[9] reported a case in which a reaction occurred in the course of the first series of injections and another when the treatment was resumed at a later date. The second reaction developed before the tourniquet was removed from the patient's leg. Both reactions were very severe but complete recovery ensued in about four hours.

For nearly two years monoethanolamine oleate (monolate) has been my solution of choice for varicose veins. This solution is made of a synthesized chemical and for this reason the possibility of its containing nitrogenous materials has theoretically been eliminated. Until the time of treatment in the case to be reported I had used this solution in the treatment of more than 200 patients and had seen no reactions of any kind following its use. I have continued to use it since and have observed no other reaction of any kind. The manufacturers have received no reports of reactions, with the exception of a few of a very mild nature. Meyer[10] observed no allergic manifestations following the use of monoethanolamine oleate in a small series of cases.

REPORT OF CASE

Miss A. S., a well developed and slightly obese white English woman aged 57, referred for treatment of varicose veins Jan. 17, 1936, had extensive varicosities of the great and small saphenous systems in both legs. She had had no previous treatment. Injections of from 3 to 5 cc. of 5 per cent solution of sodium morrhuate were given at intervals until August 10, thirteen injections having been given up to that time. There was no evidence of any type of reaction to these injections.

The condition of the legs was greatly improved, although a fair number of varicosities remained which had not been injected. However, she felt so greatly improved at that time that she did not return to the office until May 2, 1938.

A week previous to this time a superficial varicosity over the left tibia had ruptured, but the resulting hemorrhage had been readily controlled by pressure. Examination revealed a considerable number of new varicosities in addition to those which had not been treated in 1936. Many of the veins which had been previously injected could still be felt as firm fibrous cords.

Because of the interval since the use of sodium morrhuate, its use was considered to be contraindicated. May 2, 1938, 2 cc. of monoethanolamine oleate was injected into a vein in the left leg. There was no reaction and a satisfactory closure of the varicosity was obtained. May 9, 4 cc. was injected into another vein in the left leg, again with no reaction and an excellent closure.

May 16, 4 cc. was again injected into a vein in the left leg. There was no immediate reaction of any kind. As had been done after each previous injection, the leg was elevated to permit the solution to empty from the vein. The patient sat quietly for about ten minutes and then dressed. She walked about 50 feet to the front door of the office, when she felt somewhat faint. She walked back into the office and sat down in a chair, where she had a generalized convulsion, to all appearances typical of that seen in epilepsy. With it she lost consciousness. Her pulse and color were excellent. In about forty-five seconds the convulsion ceased; she became conscious and was able to talk. To all appearances she was completely recovered.

After about two minutes she said that she could not breathe and lost consciousness again, but without any convulsion or muscular spasm. She ceased breathing and within two or three minutes became pulseless. Epinephrine hydrochloride was given intravenously and then into the heart, without effect. Artificial respiration was maintained from the onset of the second episode in the reaction for about thirty minutes.

An autopsy performed by Dr. Philip Goldstein, acting assistant medical examiner, revealed nothing but visceral congestion. If the death was due to any cause other than the injected monoethanolamine oleate solution, no evidence of such circumstance could be found.

COMMENT

Apparently death in this case was due to an allergic reaction, although the clinical picture was not typical. The interval of about fifteen minutes before the onset of the convulsion, the convulsion without marked change in the pulse or the patient's color and the apparently complete recovery followed by failure of respiration and cardiac action without any appreciable response to intravenous and intracardiac injections of epinephrine, were certainly not the manifestations expected with a nitritoid reaction.

Of course, rarely an allergic reaction may be evidenced in the form of a convulsion. I have a patient now nearly 40 years of age who since childhood has had a convulsion with loss of consciousness whenever she eats cod fish and at no other time. Another patient, now 25 years of age, since childhood has had a typical grand mal convulsion with loss of consciousness whenever she eats chocolate, and at no other time.

In the present case sensitivity must have developed from the two previous injections of monoethanolamine oleate, although the previous injections of sodium morrhuate may have had some bearing on the development of the allergy, in that chemicals similar to those in monoethanolamine oleate are contained in the sodium morrhuate. Meyer[10] mentioned two patients, treated first with sodium morrhuate and then with monoethanolamine oleate without any allergic reaction, who had typical allergic reactions when injections of sodium morrhuate were resumed.

PREVENTION OR AVOIDANCE OF REACTIONS

The question of the prevention or avoidance of the reactions encountered in the course of treating varicose veins by injections is most difficult and no satisfactory answer is available at the present time.

Small test doses of the solution used may reveal a sensitivity present before treatment is started but do not point out what patients will become sensitive in the course of treatment.

Mild reactions of various types will in most cases serve to warn the surgeon that a different solution should be used. Watching for these minor reactions and using them as a danger signal will aid greatly in avoiding the development of the major reactions.

After an interval in a course of treatment, various surgeons have suggested the use of intradermal tests for sensitivity before the resumption of injections with the previously used solution. This procedure cannot be counted on to rule out all patients who will later have a severe reaction, as a full dose of the material given intravenously may cause no reaction whatever for one or more injections in the new series and then be followed by a severe reaction. I start with small amounts, from 0.25 to 0.5 cc., and gradually increase the amount until the desired dose is reached, but I do not feel that this will prevent or foretell a reaction later in the series of treatments.

The commonest time for severe reactions is on the resumption of treatment after a temporary cessation of

treatment with sodium morrhuate. Rather than to rely on the intradermal or intravenous tests for sensitization, it might be better in this circumstance always to use some other solution.

TREATMENT OF THE ALLERGIC REACTIONS TO SOLUTIONS USED FOR THE TREATMENT OF VARICOSE VEINS

For the milder types of reactions, whether they are cutaneous manifestations or minor generalized nitritoid reactions, cessation of the use of the causative drug is the only treatment required.

For the severe urticarial and asthmatic type of reaction, administration of 7, 15 or if necessary 30 minims (0.4, 1 or 2 cc.) of 1:1,000 solution of epinephrine hydrochloride will give prompt and complete relief.

For the severe generalized nitritoid reactions, epinephrine, dextrose and saline solutions given intravenously, caffeine, sodium benzoate and coramine with the application of external heat and, when necessary, artificial respiration will prevent death in nearly every case.

After any type of reaction the solution which caused that reaction should not be used for the same patient at any later time.

182 East Seventy-Ninth Street.

IS NUTRITIONAL DEFICIENCY THE BASIS OF WERNICKE'S DISEASE?

REPORT OF CASE

ARTHUR D. ECKER, M.D.
Fellow in Neurology, the Mayo Foundation
AND
HENRY W. WOLTMAN, M.D.
ROCHESTER, MINN.

In 1881 Wernicke [1] described under the formidable title "encephalitis haemorrhagica superior" a disease affecting the nuclei of the nerves to the eye muscles which leads to death in a few days. The clinical signs consist of paralysis of the eye muscles, a reeling gait and disturbances of consciousness—a terminal somnolence which may or may not be preceded by a period of excitement. This syndrome has been found occasionally in association with Korsakoff's psychosis (Bonhoeffer [1]) and with polyneuritis. Tachycardia (unassociated with fever) is common, and disturbances of breathing are sometimes observed. There is an occasional report of recovery.

Perhaps the most typical anatomic feature of the disease [2] is the distribution of the lesions, which are largely limited to the gray structures near the third and fourth ventricles and the aqueduct. Sections of the brain reveal, even macroscopically, the presence of hemorrhagic areas in the mammillary bodies, posterior corpora quadrigemina and thalami. The chief histologic changes are intimal proliferation of the small blood vessels, necroses, which may be accompanied with hemorrhage, and marked glial proliferation. Because there is no true inflammation, Spatz [1] expressed preference for the designation pseudo-encephalitis.

From the Section on Neurology, the Mayo Clinic

2. Wertham, Frederic, and Wertham, Florence: The Brain as an Organ, New York, The Macmillan Company, 1934.

Two of Wernicke's original three patients were alcoholic addicts who were admitted in delirium. The subsequent patients with this syndrome whose cases were to be reported (Jacobäus) were all alcoholic addicts Indeed, chronic alcoholism has come to be considered the basis of the condition.[2]

It is therefore interesting to recall that in Wernicke's first case (cited by Jacobäus [3]) there was no associated alcoholism:

> The patient was a 20 year old seamstress who was dismissed from the Charité Jan. 6, 1877, after recovering from poisoning with sulfuric acid. Soon after she left the institution she started to vomit but otherwise remained well. However, from February 3 she was bedridden and strikingly sleepy; she yawned a great deal and reeled in walking. Her vision became impaired, and she suffered from dizziness and headache. February 11 there were some ptosis, impairment of external ocular movements and diminution of the pupillary light reflex. Moderate swelling of the optic disks and many retinal hemorrhages were observed. She became more sleepy and disoriented, sank into coma and died February 15. Necropsy revealed punctate hemorrhages in the vessel sheaths of the tissue lining the third ventricle, in the corpora quadrigemina and in the retinas.

In 1924 Tanaka [4] observed the same histologic picture in association with an unusual condition which has been interpreted in Japan as "intoxication from mother's milk." That Wernicke's disease is found associated not only with misuse of alcohol and other exogenous intoxications but also with so-called endogenous intoxications was shown by Neubürger,[5] who reported fourteen cases of the disease without alcoholism. He included ten cases of cancer, in seven of which the malignant growth was in the stomach. In most of Neubürger's cases vomiting and loss of weight were prominent signs.

Környey [6] reported two cases in which the clinical and the histologic pictures were of Wernicke's disease but there was again no associated alcoholism. In his first case a Korsakoff psychosis started twenty days after gastric resection for cancer. In the second instance persistent vomiting occurred with recurrent carcinoma of the cervix.

In 1937 Neubürger [7] reported three cases of chronic gastritis in elderly women with preterminal disturbance of consciousness and paralysis of the eye muscles. In these cases the anatomic lesions of Wernicke's disease were observed. It is noteworthy that in each instance the entire course of the disease was marked by striking and persistent vomiting. Neubürger considered intestinal autointoxication and nutritional deficiency in the etiology.

REPORT OF CASE

A white American woman, married, was examined in 1923. At that time fractional analysis after a test meal revealed 8 units of free hydrochloric acid in each of three specimens of gastric content. In 1929 there was no free hydrochloric acid in any of four specimens of gastric content after a test meal and x-ray examination of the stomach gave normal results At this time cholecystectomy was performed.

She returned to the hospital at the age of 50, July 12, 1937, and said that for two years she had had indefinite irregular

distress and pain in the upper right quadrant of the abdomen, together with eructations. Three months before registration, at the time of an automobile accident, she had been unconscious for a short period but had suffered neither fracture nor gross trauma. Since then she had been very nervous and the attacks of severe abdominal pain had occurred more frequently. Headache had been present for six weeks and daily vomiting for five weeks before registration.

Except for some tenderness in the right side of the abdomen and a pulse rate of 120 beats a minute, general physical examination, including ophthalmoscopic examination, gave negative results. The temperature was 98.4 F. The urinalysis and routine examinations of the blood gave essentially normal results (the hemoglobin content was 12.6 Gm. per hundred cubic centimeters, the erythrocytes numbered 4,160,000 and the leukocytes varied from 5,300 to 17,500 per cubic millimeter). There was no free hydrochloric acid in the gastric content. X-ray examinations of the chest, head and abdomen showed no abnormality. Examination of the blood for bromides gave negative results. The basal metabolic rate was +12 per cent. The blood urea content was 18 mg. per hundred cubic centimeters, the carbon dioxide combining power was 46.7 volumes per cent, and the serum sulfates amounted to 3.3 mg. and the serum bilirubin to 1.1 mg. per hundred cubic centimeters. The bromsulphalein liver function test showed maximal retention of the dye. The sedimentation rate was 62 mm. an hour. A careful examination of the central nervous system gave negative results objectively. However, the history suggested an anxiety state of several years' standing.

The patient's course in the hospital was marked by continual vomiting of the regurgitant type, which required the parenteral administration of salt solution and dextrose almost daily. Her pulse rate continued to vary between 110 and 120 beats a minute, even though her temperature remained normal and there was no evidence of hyperthyroidism. Although there was some tenderness in the right side of the abdomen, the leukocyte count was repeatedly normal. The determination of serum bilirubin was repeated and the content found to be 1.2 mg. per hundred cubic centimeters; the serum yielded an indirect van den Bergh reaction. Occasionally the patient became restless, slightly agitated and depressed because of her failure to improve. The ophthalmoscopic examination was repeated by Dr. H. P. Wagener and again reported as giving negative results. Some observers felt a mass in the right side of the abdomen.

July 24 exploratory laparotomy, performed under regional anesthesia, revealed a loop of ileum which had become adherent to the site of the former right rectus incision. The pylorus and the first portion of the duodenum were adherent to the liver at the bed of the gallbladder. The rest of the exploration showed no abnormality and the adhesions were freed.

The first five days of the postoperative course were marked by much less vomiting than had occurred previously. The patient took about 2 liters of fluid a day by mouth. However, the afebrile tachycardia persisted.

July 29 the vomiting recurred and minimal fever (temperature, 99 F.) appeared. The fever recurred daily in the late afternoon and gradually increased. The pulse rate varied between 110 and 140 beats a minute. August 6 mental confusion and restlessness with continual movements of the lower limbs were observed. There was some loss of visual acuity. External ocular movements were limited in all directions, and the deep tendon reflexes were generally diminished to a slight degree. No other abnormality was found on neurologic examination, but the patient could not cooperate for a sensory examination. Dr. H. P. Wagener repeated the examination of the fundus and found a number of large hemorrhages in each retina around the margins of the optic disk and toward the macula. He found no definite edema of the optic disks. He considered the recent reduction of vision retrobulbar in origin and the entire picture suggestive of a deficiency of vitamins B and C. The blood urea amounted to 26 mg. and the blood chloride to 627 mg. per hundred cubic centimeters, the carbon dioxide combining power was 68 volumes per cent and the calcium content was 9.4 mg. per hundred cubic centimeters. Preparations of vitamin B, vitamin C and liver extract were administered intramuscularly, and parenteral injection of a solution of salt and dextrose was continued.

August 7 the spinal fluid was found to be clear and colorless. The pressure was 8 cm. of water and the protein content 45 mg. per hundred cubic centimeters. The Kolmer, Kline and colloidal gold tests were negative. There were 2 small lymphocytes per cubic millimeter. The patient's temperature ascended to 105 F. and the pulse rate to 170 beats a minute. Although the patient was comatose and breathing irregularly, her pupils reacted normally. The calves were tender. The tendon reflexes were diminished in the arms and absent in the legs. These observations were considered evidence of multiple peripheral neuritis. The parenteral administration of vitamins was continued, and a transfusion of 500 cc. of blood was given. August 8 the patient was moribund in coma. There was twitching of the facial muscles. Tenderness of the nerve trunks and of the calves was still present. The temperature remained high until death occurred August 9.

Necropsy was performed two hours after death. The brain weighed 1,080 Gm. and there was minimal atrophy of the cerebral convolutions. Petechial hemorrhages were present in the mammillary bodies (*a* in the illustration) and in the posterior corpora quadrigemina (*b*). Otherwise the brain, spinal cord and brachial and lumbosacral plexuses were normal macroscopically. There were also petechial hemorrhages in the skin over the arms and chest and in the lungs, as well as atrophy of the liver (which weighed 1,085 Gm.) and of the gastric and intestinal mucous membranes.

a, Frontal section at the level of the mammillary bodies, showing minute hemorrhages; *b*, transverse section of the inferior corpora quadrigemina, showing minute hemorrhages in the roof of the midbrain. (The lesions in the nuclei of the trochlear nerves are microscopic and are found below the aqueduct.)

Microscopic study of many areas of the brain and spinal cord revealed definite changes only in the mammillary bodies, posterior corpora quadrigemina and infundibulum. In these areas there were proliferative changes of the endothelial cells of the small vessels (marked by mitotic figures), considerable interstitial edema and small round hemorrhages, usually perivascular. The nerve cells were well preserved except in the nuclei of the nerves to the eye muscles, where there was advanced chromatolysis, and in the thalamus, where chromatolysis with satellitosis was present. In an occasional peripheral nerve (for example, from the brachial plexus) there was an area of demyelination, which contained scavenger cells. These areas represented noninflammatory degeneration.

The microscopic sections of the stomach, duodenum, jejunum and ileum revealed the mucosa to be only from a third to a half as thick as normal; thus the macroscopic impression of atrophy of the gastrointestinal mucosa was confirmed. There were moderate fatty change and slight passive congestion but no central necrosis in the liver. The microscopic picture was confirmed by Dr. J. W. Kernohan.

COMMENT

As a result of loss of essential secretions or of food, this patient undoubtedly suffered from a deficiency state which was exacerbated by the chronic atrophy of the gastrointestinal mucous membrane.[8] It is likely

8. Wilbur, D. L., and Snell, A. M.: Deficiency States Associated with Gastro-Intestinal Disease, Am. J. Digest. Dis. & Nutrition 4: 720-728 (Jan.) 1938.

that the retention of dye and the fatty change in the liver resulted from a vitamin deficiency.[9] The persistently rapid heart rate in the absence of fever or hyperthyroidism is common in cases of vitamin B deficiency.[10] The relation of the retinal hemorrhages to a deficiency in nutrition and particularly to a deficiency in vitamins has been amply demonstrated.[11] Furthermore, the patient presented all the clinical and anatomic characteristics of Wernicke's disease. Finally, the lesions of Wernicke's disease are said to have been produced experimentally by the administration of a diet deficient in vitamins.[12] It is suggested that a deficiency of nutrition, probably of vitamins, underlies Wernicke's disease in all cases. Large doses of vitamins B and C have effected a cure of this condition in some of our cases.

SYPHILIS

WITH SPECIAL REFERENCE TO THE INCIDENCE IN RELATIONSHIP TO AGE GROUPS AND STATUS OF THERAPY AT THE DATE OF INFECTION

G. H. HANSMANN, M.D.
MILWAUKEE

The recent prevalence of syphilis as claimed by the propaganda arising from the United States Public Health Service was outright astounding to me. During twenty-four years of endeavor as a medical student and worker in laboratory medicine, in the course of which time thousands of postmortem examinations, examinations of surgical specimens and serum tests for syphilis were both accomplished personally and personally directed, I have witnessed syphilis in four sections of the country dwindle from a common experience with full blown active lesions to an occasional positive serologic test, a few scars of the aorta, a rare scarred liver presumably syphilitic, a slightly more frequent syphilis scarred central nervous system, and about twice a year an actual case of congenital syphilis.

I had not insisted on a routine serologic test for syphilis because syphilis rarely was evident at postmortem and surgical specimen examinations, in the run of clinical cases, in serologic tests on prospective donors for blood transfusions, in cases in which a test happened to be made on available excess serum obtained for other purposes, and in tests done on actual syphilis suspects. The fear naturally arose that even though I thought that I had given due consideration to syphilis I may not have been thorough enough and that many cases had escaped notice because routine tests were not made.

I have therefore felt obligated to find a way to check more accurately the standard of medical practice in Milwaukee with particular reference to syphilis, in the interest of establishing a base line so that a determination might be made of what really has been accomplished in the quiet, inexpensive, determined, unobtrusive way characteristic of the dignity of the best medical practice, and what has been left for the more vigorous programs recently inaugurated to accomplish.

The objective of fair sampling requires cognizance and avoidance of pitfalls commonly inherent in statistics. Swivel chair statistics, in which the percentage of syphilis was based on the number of positive serologic tests without possession of information as to the number of individuals and consequences of the lesions represented, were eliminated. The subjects were observed in a manner which did not overemphasize the prevalence of syphilis. The figures should represent recent transmission of syphilis and not be burdened by cases in which infection may have been acquired even before the discovery of the spirochete, the advent of arsenical and bismuth treatments, and the application of serologic tests for syphilis. I believe that the plan adopted has adequately eliminated all such sources of error.

I was fortunate in having the Milwaukee Children's Hospital patients as the source of the serums. Children up to 12 years of age are cared for at the institution. Mothers with recently acquired, not adequately treated, syphilis should transfer the disease to their offspring in a high percentage of cases. The study, therefore, should be not only an index of congenital syphilis but an index of syphilis sufficiently active to be hazardous to the public in the parents of the group represented. All samples of blood were taken and tested by the laboratory personnel. All records were maintained within the laboratory. A rapid exclusion test, too delicate for diagnosis, was used to exclude negative cases. All serums of positive nature, regardless of degree, were subjected to two or more additional serologic tests at Columbia Hospital and the serologic laboratory of the Wisconsin Psychiatric Institute at Madison. All patients entering the outdoor department or hospital with the exception of a few private patients were tested. In the advent of a positive serologic test for syphilis, the entire family was investigated as far as this was possible. The cases of syphilis encountered in a family study could not rightfully be included in the statistical figure of current incidence of syphilis, since they were not seen in the regular run of cases. Only the initial case in the family was included in the statistics. The rigidly controlled plan has eliminated all possibility of the rather common practice of sending in a number of serums on the same patient under various names after obtaining a positive test. The hospital has no syphilis clinic to distort the figures of incidence. The hospital is a charitable institution and cares primarily for the children of the poor and low income families of Milwaukee. As far as there is anything to the fact that the low income group obtains inadequate medical care, the figures are probably too high. Facilities were not available to compensate for this error.

The incidence of syphilis in persons under 12 years of age indicated in table 1 would place the number of children who most likely have syphilis at 369 of Milwaukee's 123,000 children. Of these, forty have the untoward anatomic stigmas of syphilis, eighty have skeletal changes which may be determined radiologically, while 289 have only a positive serologic test to support the diagnosis of syphilis.

There were two instances in which both parents were negative to the serologic tests. The parents of one of the children had a history of syphilis, the mother

From the Milwaukee Children's and Columbia hospitals.

received antisyphilitic treatment during the final months of the gestation, and arsenic determinations on the hair indicated that the hair of the infant contained slightly more arsenic than that of the mother. At the time of the study, both parents and child had negative serums, but the child had x-ray evidence of skeletal syphilis. The parents in the second case had no history of syphilis, and the four other children had negative serums. It is not my purpose here to discuss the requirements for an accurate diagnosis of syphilis. Whether one likes it or detests it, a positive serologic test for syphilis is usually taken as a signal to turn on the spigots of antisyphilitic therapy. When one views the marked divergence between positive tests and morphologic evidences of syphilis as studied clinically, radiologically and at the postmortem table, thorough medical men must often wonder whether we do not have too implicit faith in a positive serologic test for syphilis. Certainly a child with only a positive test, with parents and four other children negative in all particulars, should raise the question of the requirements of an accurate diagnosis and proper therapeutic regimen.

If the expenditure of getting in touch with the patient, obtaining the blood, performing the test, recording the information and disseminating the information to proper authorities is fixed at $1.50 per test, it costs $712.50 in Milwaukee to make a positive serologic diagnosis of syphilis in children by the routine test method.

Assuming that the mothers who transmitted syphilis to their offspring represent the clinically active cases of syphilis and that the usual spread of three positive serologic tests to one clinically active case prevails, the incidence of probable syphilis in this 35 year age group would be 1.2 per cent. As donors for blood transfusions for their children, 210 mothers presented themselves in a routine manner. Three of these had positive Kline

Number positive	2
Percentage of mothers with syphilitic activity sufficient to transmit syphilis during a full period of gestation	0 7

tests, an incidence of 1.4 per cent. The average incidence from the two sources of information would be 1.3 per cent. This would represent the adequacy of medical practice of about ten years ago if we put the average age at 25 for acquired syphilis.

The clinical information on the doubtful case in table 2 was that of an anemic, very ill child with a positive Kline test. Neither parent had a history of syphilis or a history of treatment, and both had negative serums. Postmortem examination added a chronic pancreatitis, but the spirochete could not be demonstrated in the pancreas, liver or adrenals by the various staining methods. Consequently, this case remains very much in doubt.

The ages of the patients in table 3 who showed evidences of syphilis varied between 46 and 76. The average age was 60. If the likelihood is assumed that

these patients acquired their syphilis at the average age of 25, the management of their disease will represent the medical practice of 1903, a date which antedates the discovery of the spirochete, the Wassermann reaction or important antisyphilitic treatment other than mercury.

Even here in only one of the eight cases did syphilis operate as the major cause of death. In fact, this patient was the only one who presented a progressive syphilitic lesion: a meningovascular syphilis with occlusion of a vessel in the pons. Two patients were somewhat disabled by aneurysms of moderate size. Two patients had evidence of old quiescent tabes, one of whom was included in the aforementioned aneurysms. Another disabling scar was a syphilitic periostitis. The final patient had quiescent gummatous scars of the liver and a syphilitic cirrhosis. In two bodies, small aortic scars were found at postmortem examination. In one body, even though forewarned of a positive serologic reaction, I was unable to find a lesion of syphilis at postmortem examination. Fortunately for the patients and with no hazard to the public, six of the patients were not under active treatment. The lesions of syphilis in these cases were at an irreducible residuum. The patient with the syphilitic periostitis may still receive some benefit from treatment. One patient was inadvertently injured seriously by the treatment. Active treatment of the patient with the meningovascular syphilis most likely would have averted death. Six of the nine would have benefited by treatment before the disabling lesions developed. It seems self evident that when these elderly persons who contracted their syphilis from thirty to forty years ago drop out of the picture there will be an appreciable spontaneous drop in the incidence of syphilis.

Eight patients of the 178 in the 60 year average age group had either scars of syphilis or a positive Wassermann reaction. Five of these had clinically recognized syphilis. This would indicate that, in 3 per cent of the population of Milwaukee in this age group, evidence of active or latent syphilis could be identified on careful physical examinations. If we calculate those who have demonstrable syphilis and those who have only positive serologic tests on the basis of the usual spread of a

recognizable clinical case to three with positive serologic tests, the incidence in this age group would be 12 per cent.

The protean manifestations of syphilis are summed up well in the old dictum "To know syphilis is to know medicine." We must bear in mind that this dictum has inherent the proposition that a person who has a positive serologic test may be actually or concurrently suffering from any of the other diseases which may be interpreted as syphilis because of a positive serologic test. Experience at postmortem examination has taught me that, if the brain, cardiovascular system, liver, hematopoietic organs or kidney are vulnerable or actually diseased, the consequences of antisyphilitic treatment are too often grave. Antisyphilitic treatment is therefore not to be undertaken lightly. It should be an individual problem undertaken only under the most intimate medical supervision. The social consequences of the patient's disease, how much the patient is likely to benefit from the treatment, and actual disease and functional status of the organs named should all be taken into consideration. Close observation for inadvertent consequences is also imperative. An accurate diagnosis of syphilis is here assumed.

This actual study of syphilis was made at Iowa City, Boston, Iowa City, Washington, D. C., and Milwaukee in order of service. The study represents the period between 1916 and the present. In order of decreasing incidence of syphilis, the arrangement is Washington, Iowa City, Boston and Milwaukee. The factors responsible for the situation in a given locality seemed to be the alertness of the profession, the adequacy of consideration for care of the indigent, and the cooperation of the patient. The importance of the alertness of the medical profession, which is always coupled with willingness to serve, has been outstanding. It should be pointed out that the District of Columbia is largely dependent on the federal government for appropriations for the care of the indigent. Curiously enough, here is also the home of the United States Public Health Service.

SUMMARY AND CONCLUSIONS

1. Syphilis was studied in the various age groups in Milwaukee with special reference to incidence and the consequences of the disease as well as the relationship of the incidence to the development of means for recognition and treatment of the condition.

2. Dependence was placed on routine admissions, presentation of parents for blood transfusions, and postmortem examinations for reliable sampling of the public in the study.

3. The high incidence of syphilis which prevails in the age group who acquired their syphilis before the advent of the discovery of the spirochete, the development of important arsenic and bismuth preparations and the knowledge of the serologic tests indicates that the groundwork has been laid for an imminent spontaneous fall in the incidence of syphilis.

4. The incidence of syphilis varies from one locality to another, depending on the alertness of the profession, the cooperation of the patient and provisions for the care of the indigent named in the order of their importance.

5. There can be no intelligent discussion of syphilis on the basis of the number of serologic tests per thousand of population. The least information for an intelligent discussion would appear to be the number of individuals represented by the tests per given area, the personal and the economic consequences of the disease, what the therapy has to offer the individual, and the functional and anatomic integrity of the body resulting from causes other than syphilis and the inadvertent serious consequences of the treatment.

6. In the postmortem examinations made, in all but one the morbid anatomy of syphilis was at an irreducible residuum.

PAROVARIAN CYSTS COMPLICATING PREGNANCY

REPORT OF CASE CAUSING DYSTOCIA: REVIEW OF LITERATURE

WENDELL DOWNING, M.D.
AND
LAWRENCE O'TOOLE, M.D.
LE MARS, IOWA

Dystocia caused by a parovarian cyst is of rare occurrence. A review of the literature since 1873 shows only sixty-two [1] reports of parovarian cysts complicating all stages of pregnancy and in only seven cases did the cyst produce dystocia. This paper includes a summary of all the cases complicating pregnancy that have been reported since 1873. No such analysis has been made previously. The study was prompted by a recent case in which a parovarian cyst produced a pelvic block and required aspiration of the cyst to permit delivery of the fetus.

Ovarian cysts and solid tumors, such as myomas, may also cause pelvic block and dystocia. The solid tumors can usually be differentiated from cysts, but the differential diagnosis of ovarian from parovarian cysts is often impossible during pregnancy and labor. Vozza [2] in a review from his own clinic of 108 cases of cysts complicating pregnancy found that twenty-seven cases (24 per cent) were of parovarian origin, twenty-nine cases (26 per cent) were dermoids and in fifty-two cases the cyst originated in one or the other ovary, being bilateral in 4.5 per cent.

EMBRYOLOGY

The parovarium represents a remanent of the sexual portion of the wolffian body in the female and is a homologue of the epididymis in the male. It lies in the connective tissue of the broad ligament near the fallopian tube and consists of a main collecting channel, running close and parallel with the tube, together with from ten to eighteen small perpendicular ducts projecting toward the hilus of the ovary. Cystic dilatations of the blind end of the main channel are frequent and produce the hydatids of Morgagni, which have no clinical significance. Parovarian cysts, which

---

From the Le Mars Clinic.

Dr. Jeannette D. Throckmorton of the Iowa State Medical Library prepared our bibliography and aided in securing the case reports from her own and the Surgeon General's Library, and Drs. Poble and Carnazzo of Le Mars translated the French and Italian reports

1. After this paper had been prepared, Dr. Throckmorton accidentally found the following report of a case which is not listed in any of the indexes: A tertipara in premature (?) labor presented a mass the size of a fist in the culdesac; torsion and gangrene were present Cesarean section was performed and a cyst was removed from the broad ligament on the left side. The mother recovered, but no mention was made of the fetus. The patient had complained of constipation during pregnancy and severe pain in the left iliac quadrant after the fifth month (Johnstone: Broad Ligament Cyst with Twisted Pedicle Which Obstructed Labor. Specimen, Tr. Edinburgh Obst. Soc. 55: 25, 1925-1926; Edinburgh M. J. 33: 25-26 [Feb.] 1926).

2. Vozza, F.: Evolution of Ovarian and Parovarian Tumors During Different Periods of Pregnancy: Brief Report of 109 Clinical Cases, Ann. di ostet. e ginec. 54: 889-1073 (July 31) 1932

TABLE 1.—*Summary of Twenty-Six Cases of Parovarian Cysts Complicating Pregnancy Reported by Vozza* [2]

Case	Previous Pregnancies	Month of Pregnancy	Condition Found	Complications	Intervention	Maternal Results	Progress of Pregnancy	Observations
1	None	4th	Left cyst; 8 liters	None	Cyst emptied and removed	Cure	Normal course	Rapid growth of cyst with onset of pregnancy
2	One	2d	Left cyst, size large orange	Torsion of pedicle; intracystic hemorrhage	Removal	Cure	Normal course	No symptoms; accidental finding of tumor by patient; rapid growth during pregnancy
3	Four, three abortions	3d	Pedunculated right cyst size of fetal head at term	None	Removal	Cure	Normal course	Uterus retroverted; pernicious vomiting ceased after removal of cyst
4	None	3d	Right cyst; 3 liters sero purulent fluid	Suppuration; few pericystic adhesions	Removal	Cure	Aborted 5th postoperative day	Acute onset of fever; pain; diagnosis of cyst with torsion
5	Two	2d	Right cyst; 2 liters fluid	Torsion of pedicle, intracystic hemorrhage	Removal of cyst with adenoma	Cure	Normal course	Asymptomatic torsion, cyst anterior to uterus; displaced posteriorly
6	None	4th	Left cyst size of 7 month fetal head	None	Removal of cyst deep in pelvis posterior to uterus	Cure	Normal course	Severe constipation
7	None	8th	Right cyst, suppurating, size of fetal head at term	Suppuration of cyst in puerperium	Sac emptied and marsupialized	Cure	Spontaneous delivery of infant; died 2 days later	Pregnancy normal save for premature labor in 8th month
8	Three	Puerperium	Multiple cysts *size of 8 month* pregnancy	None	Removal 7th *day of* puerperium	Cure	Spontaneous premature labor	No disturbance in spite of size of abdomen; labor 8th month; forceps
9	Two	3d	Left cyst; 7 liters watery fluid	None	Removal following aspiration	Cure	Normal course	Cyst present prior to pregnancy; rapid growth with pregnancy
10	One abortion	2d	Right cyst; very thin wall	Torsion of pedicle, adhesions	Removal	Cure	Normal course	Torsion probable before pregnancy; tumor *in left lower quadrant*
11	None	Puerperium	Right cyst; 3 liters, hemorrhage and necrosis of wall	Torsion	Aspiration followed by removal	Cure	Operation in puerperium	Normal delivery; returned because of large abdomen
12	None	3d	Right cyst size of 8 month fetal head	None	Removal	Cure	Normal course	No developments
13	None	3d	Cyst size of orange	None	Removal	Cure	Normal course	Accidental finding of tumor by patient
14	None	2d	Cyst with two compartments	None	Removal, correction of retroflexion	Cure	Abortion 6th postoperative day	Preexisting threatened abortion
15	None	2d	Left cyst size of orange	None	Removal	Cure	Normal course	No disturbance
16	None	4th	Left cyst size of 7 month fetal head	None	Removal	Cure	Normal course	Some abdominal pain
17	Two, one abortion	3d	Size of fetal head at term	None	Removal	Cure	Normal	No subjective symptoms
18	One, one abortion	1st	Left cyst size of full term pregnancy	None	Removal	Cure	Normal	Spotting of blood after missing one menstruation
19	One, one abortion	2d	Left cyst; 7 liters of fluid	None	Removal after aspiration	Cure	Normal	Rapid growth during pregnancy
20	One	Term	Left cyst size of fetal head at term	None	Cesarean removal of cyst	Cure	Living baby	No important symptoms
21	One	3d	Left cyst size of 7 month pregnancy	None	Aspiration and removal of cyst	Cure	Normal	Rapid growth during pregnancy
22	None	Term	Left cyst size of fetal head at term	None	Cesarean removal of cyst	Cure	Live baby	Symptoms of abdominal pain
23	Three	2d	Left cyst size of adult head, cyst of right ovary	None	Removal of cyst and ovary, correct retro flexion	Cure	Abortion 8th day	Cyst accidentally found on examination
24	Two	2d	Right cyst size of fist	None	Removal	Cure	Normal	Cyst found on routine examination
25	One	2d	Left cyst size of fetal head	Torsion	Removal	Cure	Normal	Obstinate vomiting
26	None	3d	Right cyst size of orange	None	Removal	Cure	Normal	Rapid growth during pregnancy

were first mentioned by Velpeau in 1825, are regarded as resulting from retention of abnormal secretions of the epithelial lining of the parovarium.

PATHOLOGY

Parovarian cysts are usually single and unilocular and may be of any size. Rutherford [3] reports one case in which there were three cysts ranging in size from that of a pigeon egg to that of a duck egg. The cysts are always extraperitoneal or intraligamentary, and the tube lies stretched out over the superior surface of the cyst. A pedicle is not common but one may develop if the cyst grows intra-abdominally; the peritoneal layers of the broad ligament, the tube, the utero-ovarian ligament and even the ovary may be contained in the pedicle. A pedicle was present in seventeen of the sixty-two cases studied in this report.

3. Rutherford, R. Abortion with Broad Ligament Cysts and Bacillus Welchii Infection, Brit. M. J. 1: 173 (Jan. 22) 1938.

The cysts are usually pearly gray or pink with thin walls, with the peritoneal layers of the broad ligament freely movable over them owing to their subserous location. The inner surface of the cyst is smooth and glistening, but low papillae may be seen. The fluid is clear and serous and faintly alkaline and contains practically no mucin or pseudomucin. The fluid may be turbid, owing to degeneration and the presence of blood; it is innocuous and suppuration is rare. Dermoid cysts may be found in the broad ligament.[4] Ehrenberg [5] has recently reported an extraperitoneal epidermoid cyst containing sebaceous material producing dystocia at term.

4. Cases 1 to 14 inclusive in table 1.
5. Ehrenberg, C. J.: Epidermoid Cyst Causing Dystocia: Case, Journal-Lancet **58**: 149 (March) 1938.

Microscopically the cyst wall is made up of connective tissue with some smooth muscle and elastic tissue and is lined with a single layer of ciliated epithelium. Malignant change is very rare. Surrounding the cyst is the connective tissue of the broad ligament and within it are the blood vessels of the cyst, which are separate from those of the peritoneum.

CLINICAL

The clinical signs and symptoms depend on the location and size of the cyst. They grow slowly and are usually incarcerated in the broad ligament, thus displacing the uterus and causing more pressure on the blood vessels, nerves and ureters than ovarian cysts. They are rarely a factor in sterility, since the ovaries are normal. During pregnancy the enlarging uterus is

usually forced up and out of the pelvis to the side opposite that of the cyst. Pain in the back or sides and bladder symptoms are common. At term the cyst may cause dystocia first by causing an abnormal presentation, second by acting as an insuperable obstacle to the passage of the fetus through the pelvis, and third by producing a rupture of the uterus. A pedunculated cyst may be located in any position in the abdomen and not cause symptoms, being only accidentally discovered by the patient or her physician.

COMPLICATIONS

Torsion and gangrene of parovarian cysts are common in pregnancy when the cyst has a pedicle, and several such cases[6] have been reported. Gangrene may also result from prolonged pressure during labor. Torsion may develop at any period, but it is most common in the early months of pregnancy and in the puerperium. Torsion was a complication necessitating operation in fifteen of the sixty-two cases reported. Rupture of the cyst may occur as a result of compression by the uterus and fetal head or of degenerative changes in the cyst wall. Intracystic hemorrhage and suppuration are other less common complications. Premature separation of the normally implanted placenta has been reported in a case of parovarian cyst.

6 Cases 2, 9, and 11 in table 1.

DIAGNOSIS

The differential diagnosis of parovarian from ovarian cysts during pregnancy is usually not possible, and the treatment is in general the same. Occasionally the parovarian cyst and the ovary can be felt separately and thus differentiated. Parovarian cysts are usually lower in the pelvis and are more fixed than those of ovarian nature. A tense cyst and a fibroid softened by pregnancy may at times be difficult to differentiate.

THERAPY

The indications for treatment of cysts encountered during pregnancy vary with the period of pregnancy and the size and location of the cyst. If a diagnosis of parovarian cyst is made in a patient seen during the first half of pregnancy, the cyst should be removed as early as possible if it is large, particularly if it is situated low in the pelvis and is not movable. If it is small, the patient may be kept under close observation and if it does not enlarge its removal may be postponed until after the termination of the pregnancy. Torsion of the cyst, however, may occur at any stage of pregnancy and necessitate an immediate operation.

During the second half of pregnancy the cyst, if large and fixed in the pelvis, should be removed at once; if small and not incarcerated, the patient may be watched closely and operation may be delayed at least until the fetus becomes viable. A study of the sixty-two cases in this report indicates that in the majority of patients the cyst enlarges, often rapidly, during pregnancy.

If a parovarian cyst is not diagnosed until labor is imminent or in progress, several procedures are possible: First, an attempt should not be made to do a forceful delivery alongside the cyst if it is large and prevents the fetal head from entering the pelvis. Second, reposition of the cyst under anesthesia with the patient in the Trendelenburg position may be attempted. If the cyst originates in the broad ligament with no pedicle this will rarely be possible, but it may be successful if it is of ovarian origin. Third, if the cyst is incarcerated in the pelvis it may be aspirated through the posterior vaginal wall, a blunt needle being introduced close to the posterior edge of the cervix in the median line. Davidson [7] reports a case in which he was able to palpate the uterine vessels on the vaginal aspect of the cyst. During the puerperium the cyst should be removed by laparotomy, since the flabby cyst is apt to undergo torsion if it has a pedicle. In suitable cases in which aspiration is not advisable because of the danger of injuring the vessels or ureter or because of the inaccessibility of the cyst, a cesarean section should be performed, followed by extirpation of the cyst when the condition of the patient permits. A few authors advise against treatment by aspiration, but that procedure is much safer than section in most hands and it seems to us that it is the method of choice when the cyst is incarcerated below the uterus. The removal of the cyst following cesarean section is often difficult if it is deep in the broad ligament or if an inflammatory reaction is present. In an occasional case in which infection of the cyst or uterus is present, a total hysterectomy is indicated following the cesarean section.

Judging from the results obtained in the cases reported, abortion or premature labor rarely results from laparotomy and removal of the parovarian cyst, even when torsion necessitates an immediate operation. The most favorable period during pregnancy for intervention seems to be the fourth month. Complications, such as torsion, hemorrhage, suppuration or rupture, developing in cysts during pregnancy call for immediate operation, no matter what the period of pregnancy or puerperium.

7. Davidson, A.: A Case of Dystocia Due to Cyst of Broad Ligament, J. Obst. & Gynaec. Brit Emp. 42: 569-571 (June) 1935.

REPORT OF CASE

Mrs. G. M. aged 28, a quartipara, was referred to the Sacred Heart Hospital Dec. 2, 1937, by her physician, Dr. Charles Ihle of Cleghorn. Her past history revealed no serious illnesses and no operations. Her menses began at 13 years and were normal. The patient's first labor occurred in 1930; the labor was long and difficult and a stillbirth resulted. Her second labor in 1932 was normal. During her third pregnancy her blood pressure was elevated, being 170 systolic and 90 diastolic, but no toxemia developed. Her third labor, in December 1934, was normal. Following the third labor her blood pressure remained elevated and a valvular heart disease was first noted.

Her last menses before her fourth pregnancy occurred Feb. 23, 1937. During the pregnancy she felt weak and tired and had frequent headaches. There was no albuminuria or edema, but her blood pressure was 180 systolic, 100 diastolic. She had no unusual abdominal or pelvic symptoms. December 1 the patient complained of a severe headache with vertigo and blurred vision, and the following day she consulted her physician, who found that her blood pressure was 210 systolic, 110 diastolic, the urine containing four plus albumin. She was sent to the hospital at once.

On admission her temperature was normal and her pulse 120; she complained of severe headache and blurred vision. No edema was present. The heart was moderately enlarged and a double murmur was present. The urine was loaded with albumin and the hemoglobin content was 56 per cent. She was given magnesium sulfate by mouth and hypodermically; pentobarbital was given at frequent intervals and fluids were forced. Free evacuation resulted. The following day there was no improvement and her blood pressure was 220 systolic, 120 diastolic. One ounce (30 cc.) of castor oil was given and was followed by 16 grains (1 Gm.) of quinine in divided doses. Labor began in a few hours and the membranes ruptured at 7 o'clock the following morning.

Examination one hour later showed the fetal head high and to the right above the symphysis. Strong uterine contractions were felt. The cervix was very high up beneath the bladder and one had to displace the posterior vaginal wall to locate the cervix, which was partially dilated and effaced. The posterior vaginal wall was pushed anteriorly by a firm fluctuant mass which compressed the rectum and displaced the fetal head high to the right and out of the pelvis. On rectal examination a cystic mass was felt in the culdesac between the rectal and vaginal walls. The patient's pains were regular and strong but the labor progressed slowly. The blood pressure was 220 systolic, 140 diastolic. She was kept drowsy by pentobarbital sodium and at 11:30 occurred her first and only convulsion, which was quite severe. Magnesium sulfate and morphine were given hypodermically. By 1 p. m. dilatation and effacement were complete. The head was felt above the symphysis through the thinned out lower uterine segment and at each contraction it felt as if the lower uterine segment would rupture.

Dr. Roy Crowder, an obstetrician of Sioux City, then saw the patient in consultation. Under light ether anesthesia a large needle on a syringe was introduced into the cystic mass through the posterior vaginal wall near the cervix in the median line. Two hundred and fifty cc. of clear fluid under pressure was removed. The head rapidly engaged and the needle had to be withdrawn to permit delivery, which was abrupt and spontaneous. The baby was a male and weighed 8 pounds (3,630 Gm.). It was in good condition but had an incomplete harelip. The third stage of labor was normal.

The patient's postpartum period was normal. She had no convulsions or headache, her pulse was 80 and her blood pressure came down to 170 systolic, 100 diastolic. There was no abdominal pain or tenderness. On the ninth day the hemoglobin

was 65 per cent and the red cells numbered 3,400,000. No mass was felt on abdominal or rectal examination. A laparotomy was performed on the tenth day through a left paramedian incision. A small blood clot was lying free over the dome of the bladder and a few soft fibrinous adhesions were present between the left broad ligament and the culdesac. A soft flabby cyst 8 cm. in diameter was present in the left broad ligament, the peritoneal layers of the broad ligament being freely movable over the cyst. The left tube was elongated and stretched out over the superior surface of the cyst. The ovaries and right tube were normal. The left tube and cyst were removed by splitting the peritoneal layers of the broad ligament. The cyst had no pedicle and but little blood supply. The appendix, which was grossly normal, was removed. When the cyst was filled to capacity it held 500 cc. and was 12 cm. in diameter. The wall of the cyst was thick and the inner surface smooth.

After the operation there was no vomiting or distention and little pain, and convalescence was uneventful. The patient was dismissed from the hospital on the eleventh postoperative day. Two months later when the baby's lip was repaired she was *feeling well. Her blood pressure was 180 systolic, 90 diastolic,* the hemoglobin content was 80 per cent, red cells numbered 4,000,000, and the urine was free of albumin.

SUMMARY

Among the sixty-two cases of parovarian cysts complicating pregnancy that are analyzed from the literature, complications necessitating emergency operations occurred in sixteen cases. A cyst incarcerated in the pelvis caused dystocia in seven cases.

Parovarian cysts usually grow rapidly during pregnancy. They may be incarcerated in the pelvis or (as in seventeen cases) have a pedicle and be movable and be in any position in relation to the uterus. The fourth month of pregnancy is the most favorable period for intervention. Torsion is a common complication of pregnancy. Postoperative abortion after laparotomy is not common.

Parovarian cysts diagnosed in the first half of pregnancy should as a rule be removed because of their tendency to enlarge rapidly and of the possibility of complications such as torsion. In the latter half of pregnancy, early removal is indicated unless the cyst is abdominal. When dystocia results from an incarcerated cyst, aspiration of the cyst by way of the vagina when possible and delivery of the fetus by the vaginal route is the procedure of choice. When aspiration is not feasible, cesarean section and removal of the cyst then or later is indicated. No maternal deaths occurred in the sixty-two cases reported.

The Power to Think Consecutively.—In his daily work a practicing physician has little or no control over the questions presented to his mind; mainly diagnostic, they are brought to him for solution one after another in great profusion. His solutions are reached in by far the greater number of instances by no process of logical reasoning, but on the basis of previous experience or on the basis of what we call intuition, a faculty often remarkably developed. Inevitably his mental activities are chiefly of this kind. The questions are not only profuse, but diverse; the mind is jerked forcibly from one question to another. When problems relating to the mechanism of disease present themselves, as they inevitably do to the more active minds and in the earlier years, then, before a clear line of thought can be established or followed to a satisfactory conclusion, the mind is torn from its problem to be confronted with others. The practice of medicine from its very nature is destructive to consecutive thought; its continued practice weakens the very power to think consecutively, and therefore clearly, on problems relating to the nature of disease, a matter very vital to progress.—Lewis, Sir Thomas: Research in Medicine and other Addresses, London, *H. K. Lewis & Co., Ltd., 1939.*

THE AFTER-TREATMENT OF COLLES FRACTURE

FREDERICK H. AMENDOLA, M.D.
NEW YORK

Functional recovery is the yardstick by which success in the treatment of any injury to a bone or a joint is measured. In fractures of the shafts of long bones a moderate deviation of bony alinement may be compatible with a good functional result. A fracture of the shaft of the humerus which has united solidly may be consistent with a good functional recovery even in the presence both of shortening and of loss of alinement. As a general rule, however, the closer the fracture line approaches the articulating end of the bone, the more important it becomes to secure good reduction of the deformity. In certain fractures, complete restoration of function cannot be obtained unless a nearly anatomic *reduction of the fragments has been achieved. Colles* fracture belongs to the latter group.

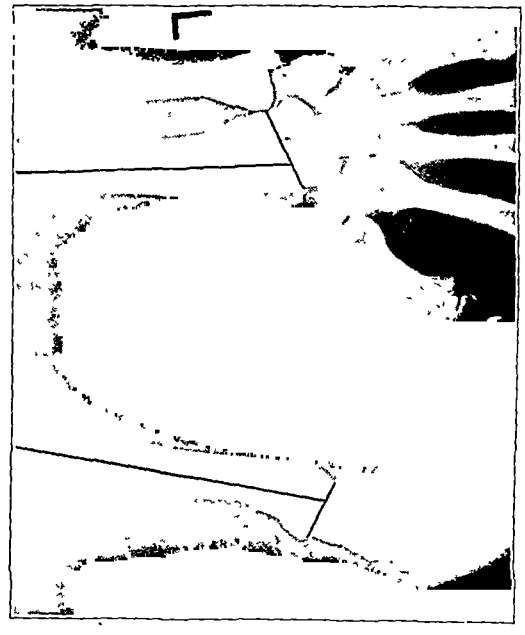

Fig. 1.—Normal wrist joint marked to indicate the forward and inward inclination of the articular surface of the radius.

Examination of a roentgenogram of a normal wrist joint (fig. 1) will reveal, among other things, that (1) in the anteroposterior view the concave articular surface of the radius faces inward at an angle of about 25 degrees; (2) in the lateral view the articular surface of the radius faces downward toward the palm at an angle of about 15 degrees, and (3) the styloid process of the radius extends distally beyond that of the ulna.

Unless reduction of a fracture satisfactorily restores these normal relationships there will be only a partial functional recovery with some persistent limitation of flexion or extension at the wrist, a persistent radial deviation of the hand and perhaps even a limited and painful rotation at the radio-ulnar joint.

A satisfactory result following Colles fracture means a complete restoration, within a reasonable time, of muscle power and motion in the hand, wrist, forearm and elbow and in the upper arm and shoulder as well.

Read before the Surgical Section of the New York Academy of Medicine, May 6, 1938.

It means free, coordinated movements of the fingers and thumb, activated by strong and supple muscles in the forearm, but it also includes a flexible elbow and shoulder which permit easy elevation of the extended arm above the head. What is meant by a reasonable time? The period naturally varies with the type of fracture and the age and condition of the patient, but in the average adult, with a fracture of average severity,

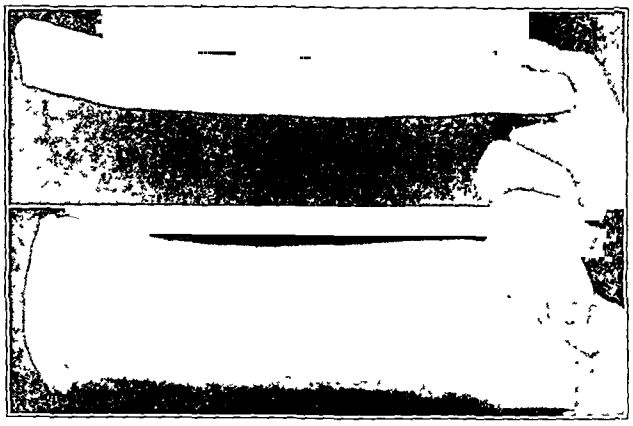

Fig. 2.—Dorsal plaster splint as seen from the side and from above.

it should not exceed seven or eight weeks. If one assumes that the fracture has been satisfactorily reduced, then the rehabilitation of the patient within the specified time depends entirely on the method of fixation of the fracture and on the after-care.

Colles fracture has been the subject of a great deal of experimentation in the matter of fixation and after-care. The invention of the plaster of paris bandage almost a hundred years ago was followed by a period during which massive heavy casts were applied to limbs. A fracture about the wrist meant the encasement of the whole arm, from the fingertips to the shoulder, in a cast which sometimes immobilized the patient as well as the wrist. On removal of the cast some months later it was the general rule to find a rigid hand, a withered arm and a deformity of a fracture which had not been reduced in the first place.

About fifty years ago, in an effort to prevent the horrible atrophy of bone and soft tissues that followed prolonged immobilization in heavy casts, Lucas-Championnière introduced early massage and early motion in the treatment of all fractures. His results were so superior to those obtained by previous methods that his practices received considerably wide acceptance within a few years. He deserves more credit perhaps than any one else for having emphasized the importance of functional recovery after injury to the bone.

The widespread use of physical therapy during and since the World War has been directly in line with the recognition of the importance of early restoration of function. The hand, wrist and forearm, because of their economic importance, have naturally become favored sites for the use of all physical therapeutic agents. These have included radiant heat, diathermy, early passive movement, early massage, electrical stimulation and ultraviolet irradiation.

Our experience at the Roosevelt Hospital with most of these agents has not been satisfactory and we have discarded all measures except active exercise in most cases of Colles fracture. We have found that other forms of physical therapy are usually unnecessary and, in some instances, may be harmful.

For many years we have followed a routine which I believe still has many advocates. Our patients were instructed to return to the fracture clinic for treatment the day following reduction of the fracture and on alternate days thereafter. These treatments consisted of radiant heat, light massage and cautious attempts at passive motion of the fingers and wrist, the fracture site being carefully supported on the anterior plaster splint and by the fingers of the operator. Active motion was encouraged as much as possible. Diathermy was begun at the discretion of the physical therapist, usually at the end of four or five days. Splints were discarded during the third week except in badly comminuted fractures, which were supported for one week longer. Heat, massage and diathermy were continued until the patient was discharged.

As time went on many practical objections to that method of after-care became apparent. The following are a few of the observations that we made:

1. Many patients were frightened at the very thought of having a splint removed for inspection so soon after the fracture had been set. Protective muscular spasm was so exaggerated that relaxed passive motion of the fingers was almost impossible in spite of gentle stroking massage and other forms of reassurance. In many patients this fear of pain on motion persisted and obviously retarded active use of the fingers in the later stages of treatment.

2. While some patients objected to any form of passive motion at the wrist, others who were less sensitive or less complaining permitted more passive motion than was good for them.

3. In a large percentage of the cases, swelling and pain in the fingers and wrist persisted for ten or twelve days after the injury. This we attributed entirely to two causes: lack of rest at the site of fracture and fear of active use of the fingers.

4. We found that simple transverse fractures almost invariably gave a good result. On the contrary, in

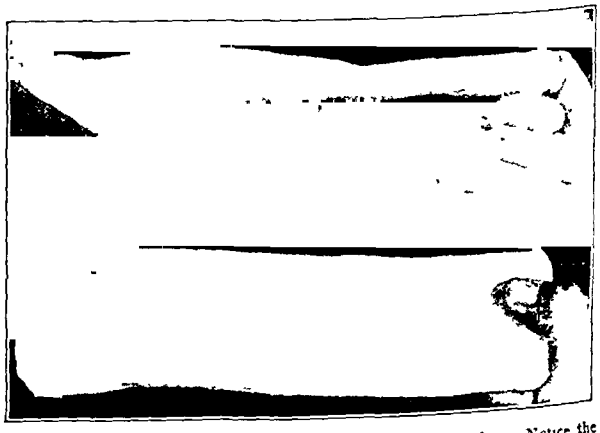

Fig. 3.—Volar splint as seen from the side and from below. Notice the portion cut away to accommodate the thenar eminence.

oblique and comminuted fractures the good position that had been obtained at the original reduction was often lost following early passive motion, in spite of every precaution. Recurrence of displacement, even when noticed early and corrected, prolonged recovery indefinitely. We saw many cases in which secondary displacement occurred during the third week of treatment.

5. Recovery of strength in the muscles of the hand and forearm was slow and was not affected appreciably by massage.

6. Diathermy did not hasten the healing of the fracture, nor did it increase the comfort of the patient.

7. We began to realize that the after-care of a Colles fracture entailed a tremendous expenditure of time on the part of the patient, the physician and the physical therapist.

About four years ago we began to abandon the use of passive motion and early massage and prolonged

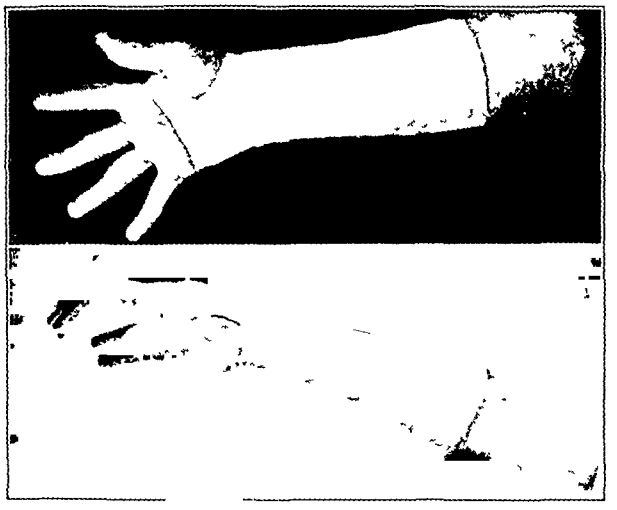

Fig. 4.—Completed splint. The thumb is entirely free and the fingers may be fully abducted. Notice in the palmar view that the plaster does not extend beyond the proximal flexion crease

the period of fixation. Today I am quite convinced that a better recovery will be obtained in a Colles fracture if one provides, first, uninterrupted fixation of the fragments until union of the bone is secured, and, second, a splint which allows complete function of every muscle and joint that does not have to be immobilized.

Our procedure at present is a simple one. If roentgenograms show a satisfactory reduction, anterior and posterior plaster splints are applied with the wrist out straight or in slight extension and with the forearm midway between pronation and supination. The posterior splint (fig. 2) extends from the upper third of the forearm to the middle of the dorsum of the hand. The anterior splint (fig. 3) extends down to the proximal flexion crease of the palm. The portion of this splint which overlaps the thenar eminence is cut away so that the thumb can be brought over to touch the base of the little finger. Both splints are lined with a very thin layer of cotton padding, and they are securely fixed with gauze bandage. The patient is instructed to start immediate active motion of the fingers. He is permitted to discard the sling at home for several hours at a time to permit elevation of the arm and flexion and extension of the elbow.

These splints are not disturbed for about five days. By that time most of the swelling will have disappeared and the splints will be ready for final adjustment. Without disturbing the splints, we remove several layers of the outer gauze bandage. A very light circular bandage of plaster is then applied over the splints and gauze. This circular bandage must be snug enough to prevent any movement at the wrist and it must be applied so that it does not interfere in any way with complete motion of the fingers and thumb (figs. 4 and 5). The patient should be able to clench the fist completely and to pick up and use a pencil or a fork without difficulty. The splint should be light enough so that the sling may be discarded completely after a few days. There is very seldom any need for further adjustment of the splints, and they are worn until the fracture is solidly healed and all danger of recurrence of displacement has passed. In children and young adults with simple transverse fractures, fixation for three or four weeks may be sufficient. Very oblique or badly comminuted fractures should be immobilized for four or five weeks, and occasionally for six. When the splints are finally discarded, no supporting bandage is necessary. The patient is instructed to begin active motion at the wrist and he is seen once a week until he is discharged.

I have found that at the end of four or five weeks bony union is firm and that the muscles of the hand and forearm, having been actively used throughout the period of fixation, are supple and strong. Not only is the wrist joint free from pain and tenderness but, in the great majority of cases, about 50 per cent of the normal excursion of the joint is present at the time the cast is discarded. I am firmly of the opinion that a great deal of the limitation of motion of the joint usually attributed to intra-articular stiffness is due to muscular shortening. There is some limitation of motion due to contraction of the joint capsule and ligaments. This, however, usually yields readily to the pull of the actively contracting muscles of the forearm. Functional recovery in the average case is complete in six or seven weeks.

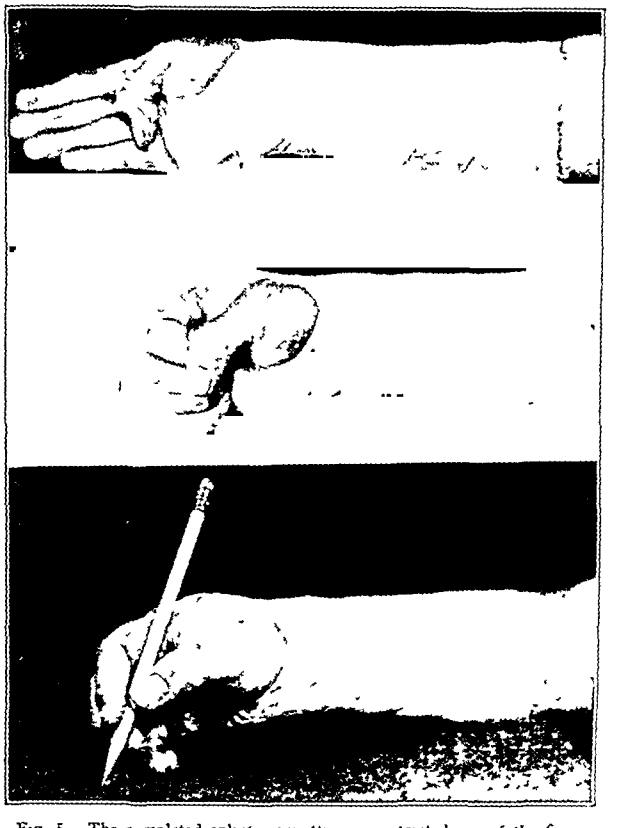

Fig. 5.—The completed splint, permitting unrestricted use of the fingers. The patient should be able to touch the base of the little finger with the thumb, clench the fist and hold a pencil without difficulty

Fractures in adults which have never been satisfactorily reduced will never have complete functional return. Severely comminuted fractures are not only difficult to reduce but difficult to maintain in good position without some form of continued traction. I have had recurrence of deformity in many cases of this

type in spite of uninterrupted and prolonged splinting. In these cases, some limitation of motion due to bony deformity at the wrist joint is common and usually permanent. It is important to note in this connection that, whereas a functional deficiency due to muscular or ligamentous shortening will be overcome almost invariably, a functional loss due to imperfect reduction will seldom disappear.

Our experience with this method of fixation of Colles fracture covers a period of approximately four years. I have found it physiologically sound. I believe that it has spared the patient a great deal of pain and that, in addition, it has permitted him greater use of the injured limb during the period of treatment. I am convinced that it has provided functional recovery within the prescribed period with less effort, with less inconvenience and discomfort and certainly with less risk than the methods hitherto employed.

CONCLUSIONS

I wish to emphasize the following points once more:

1. A good reduction is imperative; without it no method can promise satisfactory recovery.
2. The position of the fragments must be rigidly maintained by uninterrupted fixation until bony union has occurred.
3. The plaster splint should completely immobilize the wrist joint and the site of fracture, but it must permit full and unrestricted use of the fingers and thumb.

540 Park Avenue.

UNUSUAL LOCATION OF GLOMUS TUMOR

REPORT OF TWO CASES

ROBERT C. GRAUER, M.D.
AND
JAMES C. BURT, M.D.
PITTSBURGH

Our knowledge concerning the structure, distribution and function of the normal glomus has been greatly expanded since the original description by Masson [1] in 1924 of a tumor which resembled the glomus coccygeum of Luschka. Masson's description of the glomus tumor and Popoff's [2] subsequent studies concerning the distribution and alterations of the normal cutaneous glomus in conditions involving the peripheral vascular bed have stimulated interest in this subject.

It was suggested that the glomus tumor should not be regarded as a neoplasm but as an exaggerated development of a normal structure. This conception would simplify our understanding of the tumor and aid us in explaining its physiologic manifestations. Regarding its development and distribution, it is of practical importance as well as of academic interest that the normal glomus, which represents a cutaneous arteriovenous anastomosis, is not present before birth and does not begin to develop in the infant until after one month of postnatal life. Thus, the difficulty of maintaining an even, warm surface temperature in the newborn infant can now be explained on the knowledge that the inability of the infant's skin to adjust itself to sudden changes in temperature is due to the absence or paucity of these cutaneous thermoregulators. Only after the glomus bodies are fully developed does the individual appear to become accustomed to sudden changes in atmospheric temperature. On the other hand, the glomus undergoes atrophy in persons beyond the age of 60, and it is then less efficient in its thermoregulatory control of the skin. This would help to explain the difficulties that are encountered by aged persons during sudden changes of atmospheric temperature. The number of normal glomus bodies varies in different locations, and the increased number in the extremities probably speaks for a necessary accessory mechanism which helps to maintain the cutaneous temperature in those parts of the body which are most subject to sensory stimuli. These cutaneous pressure and thermoregulators have been found to occur chiefly on the palmar and plantar aspects of the hands and feet, the subungual regions of the extremities and, in lesser numbers, over the body in general. A close anatomic association of the glomus bodies with the pacinian corpuscles has been observed, and Maximow [3] suggested an accompanying functional association of these bodies with cutaneous pressure control.

Tumors of the glomus bodies have directed our attention to their physiologic activities, to their abnormal behavior and to the pathologic changes that occur in the previously normal glomus structures of the extremities in diabetic gangrene, thrombo-angiitis obliterans and arteriosclerotic gangrene.

Up to the present time about ninety tumors have been described,[4] located chiefly on the extremities and generally beneath the nails of the fingers and toes. It is of interest that no report has appeared of the occurrence of these tumors on the genitalia of either sex. Because the glomus tumor in both of our cases occurred on the penis, one in a child and the other in an adult, we consider it sufficiently important to call attention to their presence in a hitherto undescribed location.

GENERAL CHARACTERISTICS OF GLOMUS TUMORS

In from 40 to 50 per cent of the tumors recorded there was a previous history of trauma and they occurred chiefly on the hands and feet. The average duration of their presence, from the time of their appearance to the development of symptoms, was nine years. The tumors vary in size from one-eighth inch to three-fourths inch (0.3 to 2 cm.) in diameter, or slightly larger. The small tumors are usually subungual, while the larger ones are present in easily distensible tissue. The variation in size often depends on whether or not the tumor is under pressure. Pressure on the tumors not only influences their size but determines also the degree of associated pain. Most of the recorded cases presented a history of excruciatingly painful crises with radiation of the pain. All the subungual tumors were extremely painful and the mere brushing of the affected finger by the clothes or by some other light pressure would be sufficient to initiate a painful crisis. Scraping the nail to great thinness was found to reduce the amount of pressure and thus relieve the patient considerably.[5] Tumors that were located in the soft tissues, such as

on the arms or legs, and in our cases on the genitals, were usually painless. Numerous explanations have been offered for the occurrence of painful crisis, but the obvious reason is one of pressure, causing pain as a result of constriction of the nerve end organs. Though the suggested association of a disturbance of sympathetic nerves may be a factor, it has been shown in one case that periarterial sympathectomy does not give relief.[6] Complete surgical excision of the tumor produces complete relief, and recurrences have not been observed. Stout[7] records a case in which a tumor recurred after nine years, but this is the only recorded case of a recurrence and consequently one may justifiably raise the question whether excision of the tumor was complete.

Fig. 1 (case 1).—Persistent, varix-like lesion on ventral surface of child's penis.

Systematic attempts to determine whether vasomotor reactions are associated with glomus tumors were made by Stabins and his associates.[8] They made local temperature studies before and after operation on two female patients who had subungual glomus tumors of the hand. Normally there is a synchronous drop in surface temperature in the hands on being immersed in cold water. However, after patients immersed their hands in water at 15 C. it was found that recovery to their previous temperatures was more rapid on the involved side than on the uninvolved side; also that during immersion the temperature on the affected side did not drop as low as on the unaffected side. There was a difference of between 6 and 8 degrees C. on the two sides. After operation the temperature changes in the two hands were found to be synchronous. There was a vasodilatation in the skin of the affected member, which disappeared after the surgical removal of the tumor. However, the disappearance of the vasodilatation did not occur until about eight weeks after surgical excision. Owing to the persistence of some pain at the site of operation, associated with vasodilatation, the authors considered the vasodilatation of the tumors as being caused by the painful sensory stimuli. This belief was strengthened by the fact that the vasodilatation disappeared when the pain ceased. Mason and Weil[9] cited a case of Paulian and his associates in which there was an increased feeling of warmth and perspiration over the whole right side of the body in which the increase in temperature of from 0.5 to 2 degrees C. was observed on the affected side. These changes disappeared following operation. Theis[10] studied a person aged 69 who complained of intermittent claudication as a result of peripheral vascular disease associated with senile arteriosclerosis. Following treatments of alternating positive and negative pressure the circulation improved and the thermocouple temperature became normal. Six weeks after treatment for the claudication a glomus tumor appeared on the leg. This was associated with sharp, agonizing pain and was followed by a peripheral drop in temperature, probably owing to an arterial spasm caused by the tumor. Excision of the tumor brought prompt relief and a return of the peripheral temperature to normal. The observations emphasize the physiologic effects produced by these tumors and indicate the association of the glomus with the maintenance of the temperature of the skin, whether through dilatation or constriction of the vessels. Theis suggested that under pathologic conditions congestion causes swelling with pressure on the nerves and consequent paroxysms of pain, while cold causes contraction of the muscular walls of the vessels, with compression of the nerve fibers between the glomus cells and resulting pain. In either event, pressure is the important precipitating factor and whether or not the disturbance is a central one with involvement of the sympathetic system is still a moot question.

... showing the proximity of ... the cutaneous surface.

The glomus tumor can be removed only by complete surgical excision. Adair[11] attempted to apply radiation in one case, using one square radium plaque of 700 millicurie hours at 1 cm. distance and a 3 mm. brass filter. This treatment was repeated but caused no change in the tumor. Lewis and Geschickter[12] applied

four courses of x-rays to a glomus tumor which had previously been diagnosed as Ewing's tumor, with no satisfactory results. One of the cases of Stabins and his co-workers failed to respond to 50 mg. hours of radium unfiltered. Stabins considered this as a therapeutic test verifying the diagnosis of glomus tumor. In one of our cases, which we at first considered

Fig. 3 (case 2).—Section of tumor under low power

hemangio-endothelioma, four courses of roentgen treatment were given without any change in the size or character of the tumor. Two months after this treatment the true nature of the tumor occurred to us. The stubborn resistance of the glomus tumor to all means of irradiation would tend to strengthen the objection to the so-called epithelioid cells being cells of embryonic character, particularly angioblasts, since all such cells are radiosensitive. Differential stains did not enlighten us as to the possible origin or nature of the glomus cells.

Although the majority of the tumors occur singly, Weidman,[13] Bergstrand,[14] Stout and others [15] reported cases of multiple tumors. The second case reported by Bergstrand offers the additional observation that there was a diminished density of the bones of the foot in which the multiple tumors occurred, which resembled multiple cysts. The tumors in his case occupied an intra-osseous position. This occurrence had not been reported previously, though others had observed rarefaction of the phalanges, as observed by x-rays, at the site of the tumors. The pressure exerted by the expansile tumor is probably the cause of the demineralization of the contiguous bone. This appears to be a form of pressure atrophy rather than an atrophy of disuse, as was suggested by Stabins.

REPORT OF TWO CASES

CASE 1.—A boy aged 6, seen by us July 15, 1936, had a redundant prepuce with a grapelike varicosity on the inner surface of the foreskin, which became evident when the foreskin was retracted. This was about the size of a marble and had the appearance of a small cluster of veins which extended back to the ventral surface of the shaft. The nodule was a bluish purple and caused the patient no discomfort except for some pain on urination. The history obtained from the child's mother was that a bluish discoloration, similar to that observed when the child was admitted to the hospital, was first noticed when the patient was 1 year old. The redundant prepuce and the small grapelike nodule were always present, but the varix-like group of veins on the ventral surface of the penis had not been noticed. The mother stated that the child had been playing with a wagon and was hit in the region of the penis with the tongue of the wagon; it was following this that her attention was called to the varix-like enlargement. The child's past medical history and family history were irrelevant. A circumcision was performed and the foreskin and the accompanying cluster of veins were sent to the laboratory for examination.

The gross specimen consisted of two sections of prepuce, the larger section of which showed a blue discoloration on the

Fig. 4.—Section under high power showing intimate relationship of the glomus cells to the lining, endothelial cells of the Sucquet-Hoyer canal

distal portion. When cut, it was observed that numerous dilated vascular channels were filled with blood.

Microscopic examination revealed that the sections were covered by skin and contained numerous angiomatous units, which extended into the subcutaneous tissue from an area immediately beneath the cutaneous surface. In one of the larger sections there were twelve units placed close together. They consisted of circumscribed, angiomatous nodules that were

surrounded by collagen. The unit itself was characteristic of an enlarged glomus body. It contained a Sucquet-Hoyer canal, which was lined by a single layer of endothelium. The wall was made up of large polyhedral cells that contained pale acidophilic cytoplasm and deeply stained nuclei. The cells were characteristic of those which had been referred to as epithelioid cells and were several layers in thickness. Silver stains (Wilder) showed the presence both of reticulum and

Fig. 5.—Section under high power showing the nature of the glomus cells, which are several cell layers in thickness

of what appeared to be myelinated nerve fibers. There were small arterioles and venules in the capsular areas, which apparently represented the nutrient vessels of the glomus. In some areas the glomus cells were in intimate contact with the endothelial lining of the vascular spaces, while in others they were separated by smooth muscle and collagen. The outstanding microscopic picture was the nature and arrangement of the glomus cells which surrounded the vascular channels and blood vessels. The cells resembled small nests of epithelioid cells, although the origin could not be determined. No mitotic figures were seen in any sections.

The diagnosis was glomus tumor of the penis.

CASE 2.—A man aged 25 presented himself in the surgical outpatient department with an angiomatous-like lesion on the penis. The patient stated that early in infancy a small red "pimple" appeared on the penis. When the patient was 14 he was hit with a baseball bat in the region of the genitals and the previously nonpainful nodule became swollen to the size of a walnut. It subsided shortly after this and assumed the size observed when he presented himself for treatment. Whereas the tumor was nonpainful previous to the injury, it became painful on pressure subsequent to it. The tumor was situated on the left dorsolateral surface of the penis about 3 cm. from the corona and measured 1.5 by 1 cm. The appearance in situ was that of a solitary varix. It was silghtly raised above the skin, was ovoid and did not pulsate. Pressure on the lesion did not cause blanching. On dissection the nodule was found to be composed of numerous vascular channels and did not have a proximal and peripheral blood supply like a varix but was fed and drained by numerous vascular channels that extended in several directions.

The specimen received in the laboratory consisted of two small pieces of cutaneous tissue which showed the presence of several dilated veins within their substance. On section these were found to be filled with blood and closely resembled varicose veins.

Microscopically the section showed a cluster of vascular channels which were lined by a single layer of endothelium. Immediately around the endothelial lining were cells that were two and three cell layers in thickness. They were polyhedral and contained acidophilic cytoplasm. The supportive tissue about the vascular spaces was collagenous. The cells had the appearance of glomus cells, and silver stain (Wilder) showed the presence of neuroreticular material.

The diagnosis was glomus tumor of the penis.

COMMENT

Popoff made an exhaustive study of the glomus units of the body in normal and pathologic conditions. He described the normal glomus as consisting of an arteriovenous anastomotic unit which was made up of an afferent artery; the tortuous Sucquet-Hoyer canal, which consists of a narrow lumen lined with endothelium and surrounded by a thick mantle of so-called epithelioid cells (of doubtful nature); the argentophilic fibers about the Sucquet-Hoyer canal; the primary collecting veins, and, finally, an outer lamellated encircling layer of collagen. He found that the distance from the inner surface of the epithelium of the skin to the glomus in the fingers and toes is about 0.5 to 1 mm.

Fig. 6.—Silver stain (Wilder) revealing the argentophilic fibers among the glomus cells

He further observed the pertinent fact that there was no particular relation of the glomus body to the pacinian corpuscles. In his discussion of the quantitative distribution of the Sucquet-Hoyer canals he made no mention of their distribution in the male genitalia, nor were we able to find any other reference to them in this location. Because of the complex vascularity of the penis,

the finding of two tumors in this location would indicate that both normal glomus structures and possibly glomus tumors are more common here than is generally considered.

There is sufficient evidence to support the fact that the glomus is a factor in changes in cutaneous temperature. The implied alterations of cutaneous pressure have less evidence to support them. The studies of Popoff which showed the state of the glomus in arteriosclerotic and diabetic gangrene, as well as in thrombo-angiitis obliterans, may well raise the question of their association with blood pressure changes of known and unknown etiology. Cole and Sroub [16] reported the presence of a painful glomus tumor on the finger of a woman aged 33 who had a blood pressure of 200 systolic, 110 diastolic. This may have been a mere coincidence, although it possibly suggests a sympathetic nervous disturbance which had expressed itself through the development of a glomus tumor. This may seem a bit far fetched but should be borne in mind in cases of so-called essential hypertension. Stout emphasized the predominance of glomus tumors among members of the Jewish race and suggests that the predominance of disturbances of the sympathetic nervous system in this group may be a factor in explaining the comparatively high incidence of glomus tumors among the Jews.

Popoff's studies failed to show that there was a primary specific change in the glomus system associated with thrombo-angiitis obliterans. The changes that occur in the arteries, veins and skin of the digits in this condition are attributed by him to an unknown vascular anomaly rather than to a disturbance in the glomus bodies.

We call attention to the fact that true thrombo-angiitis obliterans, which occurs independently of increased vascular tension, shows no pathologic changes in the glomus, while sclerotic gangrene and diabetic gangrene, both of which are commonly associated with an increased blood pressure, do reveal definite demonstrable pathologic changes. There is a difference in predilection of the pathologic changes in the various units of the glomus body in the two conditions. In the case of diabetic gangrene, hyaline degeneration appears in the intima of the Sucquet-Hoyer canal and in the preglomus arterioles, while the intima of the afferent artery remains intact. In sclerotic gangrene the hyaline degeneration is limited to the afferent artery of the glomus. Consequently, in those conditions in which increased blood pressure becomes a fixed state, comparable sclerotic changes can be observed in the glomus bodies of the digits, whereas in a condition such as in thrombo-angiitis obliterans, in which there is an absence of increased vascular tension, the glomus bodies are uninvolved. Cases of thrombo-angiitis obliterans represent a much younger age group than do those exhibiting diabetic and sclerotic gangrene, and it may be that the hyaline changes are an expression of degeneration associated with advanced years and may have no bearing on the general condition of hypertension. But the importance of the peripheral vascular bed in explaining vascular tone and the hypertensive state is so generally conceded that any additional facts which may elucidate this problem are worthy of serious consideration.

The high incidence of associated trauma (50 per cent) with these tumors raises the question of whether there might not be a congenital weakness in the glomus bodies in the affected persons which manifests itself in an overdevelopment following injury, producing what is recognized as a glomus tumor. In both of our cases the tumors appeared on the prepuce when the patients were at least 1 year old. Whether the varix-like condition on the under surface of the shaft was always present in our first case and attention was drawn to it by the injury or whether it followed the injury could not be determined. The history of trauma precipitating a preexisting abnormality was more definite in the second case. We were unable to find any reports of the tumors appearing in patients at the age of 1 year though Adair reported one case in a child of 6 years. The implication in this case is that glomus bodies make their appearance on the male genitals as early as 1 year of age, if not earlier.

We reviewed the sections of 122 tumors of blood vessels that had been examined in this laboratory and were unable to find any other glomus tumor of the penis.

In our microscopic studies we were able to demonstrate the various elements that are necessary for the diagnosis of a glomus tumor, including the demonstration of the argentophilic fibers about and among the glomus cells of the Sucquet-Hoyer canals. In this connection we are inclined to agree with Slepyan [17] that the argentophilic fibers resemble reticulum more than they do nerve fibers.

BERIBERI SECONDARY TO HERNIA OF THE MESENTERY

LUDWIG M. LOEB, M.D.
AND
REGINA STOLZ GREENEBAUM, M.D.
CHICAGO

Cases of beriberi resulting from inadequate absorption of vitamin B_1 as a consequence of prolonged vomiting in such conditions as pyloric obstruction or pregnancy, prolonged diarrhea, or short circuiting of the bowel have been reported, but in none was the disease as severe as in ours, nor, as far as we know, have all three etiologic factors previously occurred in the same case.

REPORT OF CASE

History.—E. G., a white man aged 39, who had been confined to bed for about two months because of paralysis of the lower extremities, was first seen by us Feb. 21, 1938. His nervous symptoms began early in December 1937, with numbness in the epigastrium. The numbness gradually spread downward over the lower part of the abdomen and the medial surfaces of the thighs and ultimately involved the entire lower extremities. Pain in the legs, insteps and arches began at about the same time. Weakness of both lower limbs followed shortly, so that by December 20 the gait was unsteady. December 28 the patient fell to the floor, unable to support his weight, and since that time had not been able to walk. Atrophy of the muscles of the lower extremities appeared rather suddenly toward the end of December, when the patient lost 10 pounds (4.5 Kg.) in a single week. About a month later numbness, then weakness and finally atrophy of the upper extremities appeared, but the paresthesias and weakness were not as severe in the upper as in the lower limbs. The sphincters functioned normally. The voice was reduced to a whisper during the first two weeks of January 1938 but recovered spontaneously. No other history of cranial nerve involvement was obtained. The only mental symptom was occasional disorientation in time and space. The temperature

was not elevated at any time. The spinal fluid, obtained January 25, was clear and under normal pressure and was normal cytologically, chemically and serologically. The Wassermann test of the blood was negative. The spine appeared normal roentgenographically. Prostigmine was administered during January but the muscular strength diminished steadily. The patient had been a machinist but had never worked with heavy metals, nor was he addicted to alcohol.

The first cardiovascular symptom was edema of the eyelids, appearing late in November 1937, before the onset of the nervous symptoms. It lasted only a few days at that time but reappeared in January 1938 and became much more extensive, involving the back and the distal portions of all four extremities. The urine was consistently normal. Orthopnea and constant dyspnea at bed rest, with frequent paroxysmal exacerbations, began about February 1 and were growing more severe.

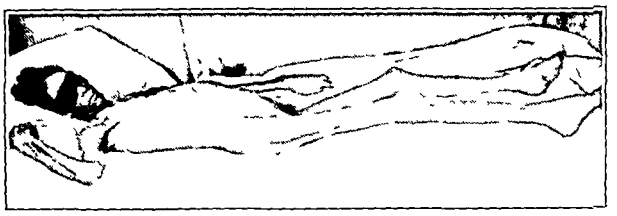

Fig. 1.—Appearance of patient March 15, 1938, showing extreme generalized muscular atrophy. The edema had disappeared everywhere except from the feet.

The patient had had intermittent postprandial epigastric distress relieved by food, alkalis or vomiting since he was 10 years old. At the age of 18 an appendectomy and inguinal herniotomy on the left were performed in the hope of ameliorating his gastrointestinal symptoms, but recurrences were as frequent after the operations as before. In May 1925, when the patient was 27 years old, frequent vomiting occurred. A posterior gastro-enterostomy was supposed to have been performed at this time to relieve obstruction produced by a cicatrizing duodenal ulcer. For the next three and a half years he was entirely free from symptoms and subsequently had only mild recurrences until January 1937, when persistent vomiting again occurred. January 30 the abdomen was explored; no previous artificial connection between the stomach and any other abdominal organ was found, and a posterior gastrojejunostomy was done. The emesis stopped postoperatively, but diarrhea began during February and became so severe that the patient had from four to eleven stools a day. No blood, pus, ova, parasites or pathogenic bacteria were found in the stools, nor did the patient have fever. From May to September he worked in spite of the diarrhea, but toward the end of this period vomiting recurred and he became so thin and weak that he went to a hospital for observation.

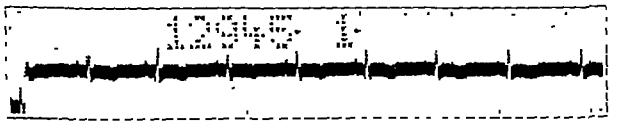

Fig. 2.—Lead 1 of an electrocardiogram taken March 8, 1938, after two weeks of thiamin therapy. Note inversion of the T wave.

He did not improve with bed rest, and insulin and dextrose administered parenterally. On the basis of roentgenologic studies it was decided that the vomiting occurred because food went through the pylorus and returned to the stomach through the gastrojejunostomy opening, thus forming a vicious circle. In the hope of breaking it a jejunojenostomy was performed in October. The diarrhea immediately ceased but emesis became worse. The patient vomited as much as 2,000 cc. at a time about once in thirty-six hours during November and December. In January 1938, about one month after the onset of the nervous symptoms, the vomiting spontaneously subsided. The patient's appetite remained good during most of his illness, but he lost about 50 pounds (23 Kg.) from his maximum weight. He had been eating a full diet since May 1937 except during the immediate postoperative period in October and had been free from epigastric distress during this time. Toward the end of January 1938 several teeth which had hitherto been in good condition broke during mastication.

Physical Examination.—When we first examined the patient, Feb. 21, 1938, he appeared almost moribund. He was dyspneic, orthopneic, pale and very emaciated, with extreme atrophy and flaccidity of all the muscles of the extremities and trunk and marked pitting edema of the face, back, hands, legs and feet. The alae nasi dilated with each inspiration, and the accessory muscles of respiration were used. The veins in the neck pulsated forcibly.

The oral mucosa was pale. Portions of several teeth were missing. The tongue was deeply furrowed and bright purplish red The gums were firm and pale.

The cardiac pulsations were diffuse, forceful and plainly visible in the second, third and fourth left interspaces, indicating enlargement especially of the right side of the heart The apex was in the fourth interspace 5 cm. to the left of the nipple line and the right border 1 cm. to the right of the sternum. No murmurs were heard. The rate was moderately rapid and the rhythm regular. The blood pressure was 130 systolic and 70 diastolic. The systolic sound over the partially compressed brachial artery was extraordinarily loud and booming. The skin was everywhere warm and smooth, and the palms of the hands were unusually pink in spite of the paralysis, edema, anemia and absence of fever. The back was so edematous that satisfactory examination of the lungs was impossible posteriorly. Anteriorly they were clear.

The abdomen was tensely distended and tympanitic, with borborygmus continuously audible even at a distance from the patient. Peristalsis was constantly visible in all parts of the abdomen and was especially noticeable in an incisional hernia in the epigastrium at the site of the last three operations.

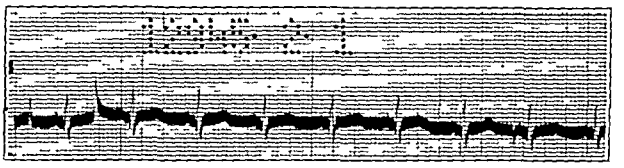

Fig. 3.—Lead 1 of an electrocardiogram taken March 24, 1938, after four weeks of thiamin therapy. The T wave is now erect.

The patient could not move his toes, ankles or wrists; motions in the knees and fingers were minimal, and in the hips, elbows and shoulders only a little stronger. He was unable to turn from side to side in bed. The extreme degree of atrophy is indicated both by the photograph taken after the edema had almost disappeared (fig. 1) and by the following measurements: maximum circumference of calf 8¼ inches (21 cm.) right, 8⅛ inches (20.6 cm.) left; circumference of thigh 8 inches (20.3 cm.) above the patella 9¼ inches (23.5 cm) right, 9¼ inches (23.5 cm.) left; circumference of forearm 1 inch (2.5 cm) below the internal condyle 7⅞ inches (20 cm.) right, 8 inches (20 3 cm.) left, and circumference of arm 1½ inches (3.8 cm.) above the internal condyle 6¼ inches (15.9 cm.) right, 6⅜ inches (16.2 cm.) left. The biceps, triceps, patellar, achilles tendon, abdominal, cremasteric, and plantar reflexes were absent. Tenderness of the gastrocnemii was exquisite. Perception of pain and touch was impaired on the lower part of the abdomen and all four extremities, more extensively in the lower than in the upper, and more severely in the distal than in the proximal portions. Proprioception was absent in the knees, ankles and toes. The cranial nerves were all normal.

The patient's hemoglobin content was 62 per cent by the Dare method, the red blood cell count 3,160,000 and the white cell count 3,150, with 79 per cent neutrophils, 1 per cent eosinophils, 10 per cent lymphocytes and 10 per cent monocytes. Anisocytosis, poikilocytosis, polychromatophilia, occasional macrocytosis and the presence of rare nucleated red cells were revealed by the smear.

Diagnosis.—On the basis of the multiple neuropathy in the absence of alcoholism or contact with heavy metals, the edema, the enlargement of the right side of the heart and the peripheral vasodilatation, one of us (L. M. L.) made a diagnosis of

beriberi resulting from lack of absorption of vitamin B_1 as a consequence of the vomiting, diarrhea and short circuiting of the bowel.

Thiamin Therapy and Its Results.—Treatment with intramuscular injections of thiamin chloride (crystalline vitamin B_1) was begun February 23 with 25 mg., and the dose was repeated February 26. Beginning March 1, daily injections of 10 mg. were given for five days, then 25 mg. daily for

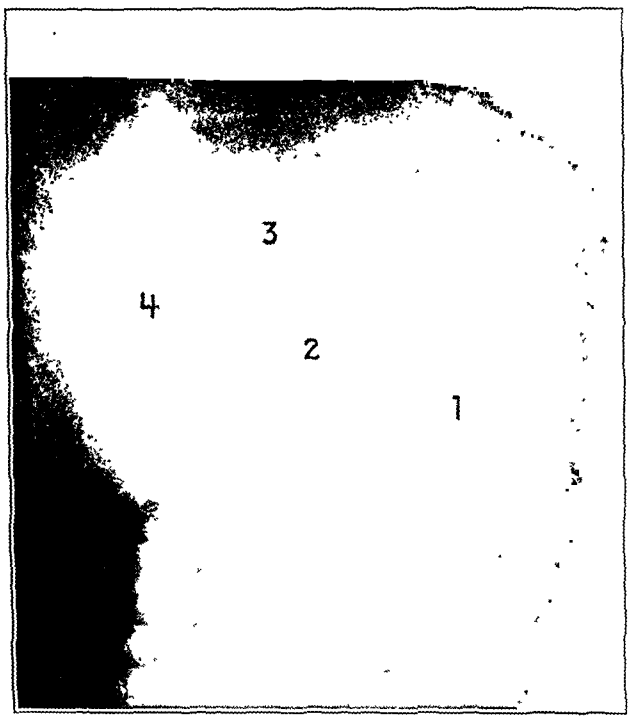

Fig. 4.—X-ray appearance Jan. 22, 1937: 1, greatly dilated pylorus; 2, duodenal cap; 3, duodenal ulcer scar, and 4, enormous dilatation of the duodenum distal to the ulcer.

fifty days and thereafter 10 mg. daily. The parenteral route was chosen both because of the severity of the deficiency and because the disease originated from faulty intestinal absorption. The day after the first injection the edema of the hands had diminished appreciably. By the time the patient entered Michael Reese Hospital in the service of Dr. Sidney Strauss nine days later the edema of the back was gone and that of the extremities greatly diminished. Within a month it had entirely disappeared. The dyspnea and orthopnea were relieved at about the same time. The pulse rate, which had been about 80 during the various periods of hospitalization in 1937 and had ranged between 100 and 130 during the last two weeks of January 1938, dropped to 50 three days after the first injection and then gradually rose to between 80 and 100. The size of the heart, as determined by percussion, also decreased, and the visible pulsations in the second, third and fourth interspaces became less conspicuous. In the electrocardiogram taken March 8 (fig. 2) the T wave in lead 1 was inverted, a change occurring frequently in beriberi. By March 24 it had become upright (fig. 3). March 8 the circulation time, determined by the calcium gluconate method, was fifteen seconds, a normal rate. The circulation time is usually decreased in patients whose decompensation results from subvitaminosis B_1 or thyrotoxicosis, in contrast to its increase in all other forms of decompensation. However, its return to normal is one of the first evidences of improvement in beriberi heart disease, and since the patient had been under treatment for two weeks when the determination was made, this result is consistent with the diagnosis.

Improvement in the nervous system was less prompt and less complete than in the circulatory system but was nevertheless progressive. About ten days after therapy was instituted, the patient lifted a handkerchief from the bed, an act he had been unable to perform for more than a month previously. At the end of two weeks he was able to grasp and lift a heavy pen knife. After three weeks he turned his body enough so that he fell out of bed as he was going to sleep. He could extend his wrist against gravity after six weeks, and at the end of ten weeks he had sufficient control to pick up a nickel from the bed. Sensory disturbances undoubtedly interfered with his ability to perform skilled acts. The strength of the muscles in the lower extremities improved correspondingly except that no recovery was observed in the muscles moving the ankles and toes. Tonus gradually returned in the various muscle groups. Although nothing had been done to prevent contractures prior to the time we first saw the patient, none had appeared. However, as the tonus improved, contractures began to develop in the gastrocnemii and hamstrings. Treatment with plaster splints and passive exercise were instituted. The right cremasteric, right upper abdominal, both biceps and both triceps reflexes returned.

The patient's response to tests of sensation varied from day to day and was always better in the morning than in the evening. Improvement was therefore rather difficult to evaluate, but over a period of weeks it was evident that sensory perception was returning. At the initial examination, perception of pinprick was lost on the dorsal surfaces of both hands and on the volar surfaces of the digits and was impaired on the anterior surface of the right upper extremity almost as high as the axilla. By May 10 pinprick produced a sharp and burning sensation in all distal phalanges and was perceived on the remainder of the hands as only slightly dull instead of entirely absent. No impairment in sensation was noticeable above the wrists at this time. In the lower extremities, as in the upper, more improvement occurred in the proximal portions. Pain perception had been impaired throughout the lower limbs and lower part of the abdomen at first. May 10 it was normal down to several inches below the inguinal folds. In the right foot, which had formerly been totally anesthetic, pinprick was perceived as a burning sensation. As early as April 1, perception of cold had returned to the right foot. As sensory perception improved, he complained more of pain and paresthesias. He stated, for example, that his hands felt "swollen and heavy" after the edema had disappeared, although when it was present he had not mentioned this sensation. Allochiria was observed in the thighs April 6. Tenderness of the gastrocnemii diminished progressively. Proprioception returned in all the joints except those of the toes but remained incomplete in the ankles. Disorientation became retrograde only.

Course.—Although the nervous and cardiovascular systems improved under thiamin therapy, the patient, who was 5 feet 10 inches (178 cm.) tall and weighed only 94 pounds (42.6 Kg.) after the edema had disappeared, failed to gain weight and had persistent symptoms of gastric retention. His appetite, ravenous in the morning, was nil toward evening, when he felt too full to eat even when he did not vomit. April 8 emesis began again, and it recurred every few days, always late in the afternoon. This, together with the persistent loud borborygmus and visible peristalsis in both the stomach and the bowel, indicated that partial intestinal obstruction was present. A careful inspection of the roentgenograms taken in January, April and October 1937 and on April 27, 1938, revealed that in each of them the entire duodenum as well as the stomach was enormously dilated (fig. 4). It was therefore evident that the obstruction did not arise from the ulcer in the duodenal cap but was distal to it, perhaps in the region of the ligament of Treitz, and that it had not been relieved by any of the previous

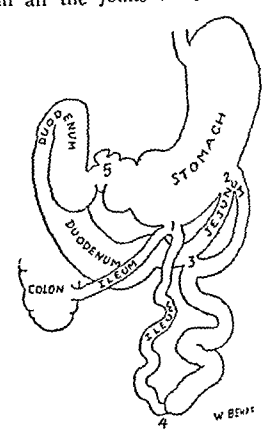

Fig. 5.—Diagram of the gastrointestinal tract as it was found at operation May 16, 1938: 1, gastroileostomy, May 1925; 2, gastrojejunostomy, January 1937; 3, jejunojejunostomy, October 1937; 4, site of hernia in mesentery, and 5, duodenal ulcer scar.

operations. Because it was thought that the patient could never become entirely well unless his assimilation of food could be improved, it was decided to explore the abdomen again.

Operation.—May 16, after two preoperative blood transfusions, an exploratory laparotomy was performed by Dr. Alfred Strauss with the patient under cyclopropane anesthesia. The stomach was enormously hypertrophied and dilated, and the duodenum was about the size of a normal large bowel.

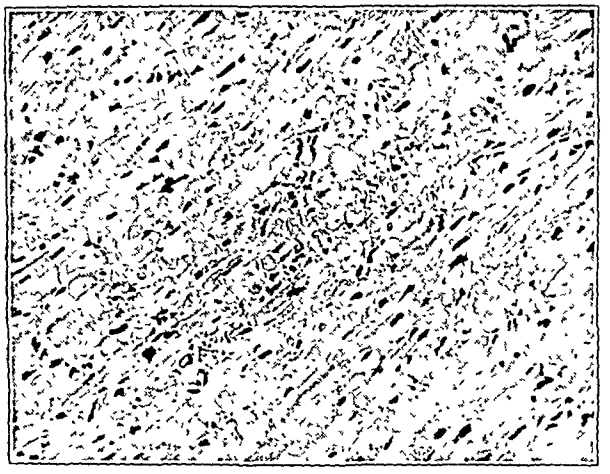

Fig. 6.—Section of myocardium, showing edema and disruption of muscle fibers and increased amount of loose areolar tissue.

The entire small intestine was brought outside the abdomen for examination. It was distended, but no vascular strangulation was observed. Three different anastomoses were found, one between the stomach and the terminal part of the ileum at a point about 1 foot from the cecum, presumably done in May 1925; another between the stomach and the proximal part of the jejunum, and a third between two loops of jejunum, one proximal to the gastrojejunostomy and the other distal to it (fig. 5). The obstruction was distal to the jejunojejunostomy passage and was produced by a congenital defect in the mesentery through which about 15 feet of small bowel had herniated. It was located midway between the ligament of Treitz and the cecum. Moderate constriction of the bowel by the hernial ring was responsible for the partial obstruction. The hernia was reduced, the defect in the mesentery was repaired, the three anastomoses were cut apart, and the six stomas thus produced were closed, restoring the gastrointestinal route to normal.

Although the operation lasted for three hours and the patient appeared to be a poor operative risk because of his long illness and extreme emaciation, the postoperative course for the next few days was remarkably uneventful. The temperature remained normal, the pulse rate did not rise above 80 and almost no abdominal pain was experienced. Borborygmus was no longer audible. Wangensteen drainage was discontinued May 19, when the patient began to eat well. May 20, however, mild diarrhea developed, followed by slight fever the next day. The abdomen, which had not been distended after the operation, again became tense, abdominal pain followed and the temperature and pulse rate rose. In spite of the reinstitution of Wangensteen drainage, numerous blood transfusions and the parenteral administration of adequate amounts of fluid, the patient grew steadily worse, and he died May 27, eleven days after the operation.

Autopsy.—The essential pathologic changes found at necropsy by Dr. Otto Saphir were a perforation of the recently closed stoma in the terminal part of the ileum with generalized fibrinopurulent peritonitis, severe edema of the myocardium, severe intraneural connective tissue edema and myelin sheath degeneration of the peripheral nerves, and caseous tuberculosis of the periaortic and peritracheal lymph nodes with encroachment on the tracheal wall.

The stomach, which had been enormously distended at the operation eleven days earlier, had contracted to normal size. The rugae were elevated, coarse and hyperemic, indicating that chronic hypertrophic gastritis was present. A recent ulcer was found in the stomach immediately adjacent to the more distal freshly closed stoma, but this had not perforated. The duodenum just beyond the pylorus contained two diverticula with intervening scar tissue, evidently the site of the old duodenal ulcer. In the region of the three recently closed ostia in the proximal part of the jejunum, a puckering of the mucosa constricted the lumen to some extent. The ostium in the ileum, through which intestinal contents had escaped, contained some loose and some broken sutures.

The heart weighed 250 Gm. and its shape was normal. In microscopic sections in some areas the muscle fibers were disrupted and more or less replaced by loose areolar connective tissue in which were numerous small empty spaces, while in other areas the cross striations were obscure and the muscle fibers granular and atrophic (fig. 6).

The brain and spinal cord were normal. In sections of peripheral nerves (fig. 7) marked edema was seen between the individual nerve fibers. Between the nerve bundles, edema and an increased amount of loose areolar connective tissue were present. Vacuolization and fragmentation of some of the nerve fibers and the presence of many large mononuclear cells were noted. In Weil myelin sheath stains, swelling and fragmentation of some of the myelin sheaths, with much replacement of the nerve fibers by connective tissue, were observed.

All the voluntary muscles were severely atrophied, and cloudy swelling was present in some of the fibers.

Tubercles were found in the peritracheal and periaortic lymph nodes and in those surrounding the right common carotid artery as it ascends into the neck. A solitary tubercle was seen in the spleen. In a microscopic section of the trachea, the encroachment of the caseous tubercles on the lumen was confirmed by the complete absence of cartilage and the presence of necrotic material immediately beneath the mucosa.

COMMENT

Nutritional Deficiencies.—In view of the cause of the subvitaminosis B_1 it was reasonable to suppose that other dietary deficiencies might be present. No means for testing the adequacy of vitamin A nutrition were available other than observation of the skin and conjunctivas, which were normal. Pellagra was not present, since the patient did not have dermatitis or stomatitis, and neither the gastrointestinal nor nervous symptoms were characteristic of this disease.

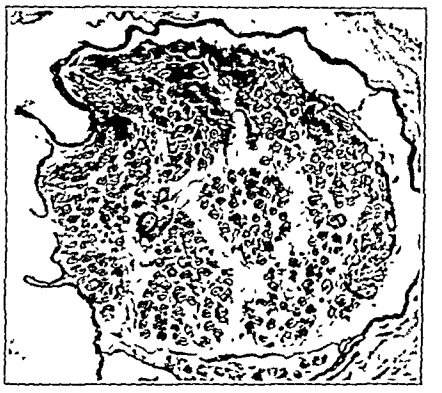

Fig. 7.—Section of peroneal nerve. Note the edema between the nerve fibers and nerve bundles and the increased amount of areolar tissue between bundles.

Furthermore, the gastric juice contained 18 units of free and 84 of total acid. Yeast cells were seen in the gastric contents, confirming the presence of free hydrochloric acid. No clinical evidence of scurvy was observed. Adequate tissue saturation with vitamin C was confirmed by the excretion of 65 mg. of ascorbic acid in the urine in twenty-four hours with the patient

on his usual diet, the normal daily urinary excretion being from 30 to 45 mg. The presence of vitamin D in adequate quantity is indicated by levels for blood calcium of 9.3 mg., for blood phosphorus of 2.6 mg. and for serum phosphatase of 3.4 units, all within normal limits for adults.

Although no other vitamin deficiency was found, other types of deficiency were present. The total blood protein content March 7 was only 5.4 Gm. per hundred cubic centimeters, with 3.4 Gm. of serum albumin and 2.0 Gm. of serum globulin. Possibly the edema was to some extent a result of hypoproteinemia, although its rapid disappearance with thiamin therapy without change in the diet indicates that it was more likely cardiovascular in origin. Another evidence of some type of deficiency was the persistence of hypochromic, macrocytic anemia in spite of daily parenteral doses of liver extract for several weeks and iron given both by mouth and parenterally. Only 0.5 per cent of reticulocytes were present March 15 even with the stimulus of liver therapy. This is less than the percentage found in normal blood. The red cell count and hemoglobin content remained essentially unchanged until a blood transfusion was given April 22, when they rose slightly. A more marked rise to 4,740,000 with a hemoglobin content of 80 per cent occurred after a second transfusion May 12. The breaking of the teeth was probably also a result of some type of nutritional deficiency, the nature of which we do not know.

The most striking evidence of insufficient absorption of food was the failure of the patient to gain weight. In spite of a high caloric, high protein, high vitamin diet his weight remained about 94 pounds (42.6 Kg.) during more than two months in the hospital. Yet food stayed in the gastrointestinal tract long enough for absorption to take place, for bowel movements, though copious, ordinarily did not occur oftener than once a day. At first we thought that some of the gastrointestinal symptoms might be a result of the subvitaminosis B_1, but the longer we observed the patient the more apparent it became that partial obstruction must be present.

Dosage of Thiamin.—At first a daily dose of 25 mg. was given to make sure that the patient was receiving an adequate amount of the vitamin. This was later reduced to 10 mg. daily, and progress was just as rapid with the smaller as with the larger dose.

Hernia of the Mesentery.—The type of mesenteric hernia found in this patient, involving the upper portion of the jejunum, is exceedingly rare. In 1932, only thirty-two cases had been reported in the literature.[1] Although it may have been a congenital defect, presumably it produced no symptoms until January 1937. All the preceding gastrointestinal symptoms can be accounted for on the basis of the old duodenal ulcer, but during and subsequent to January 1937 the symptoms were probably a result of low grade obstruction produced by the unrecognized hernia, complicated by the various anastomoses. The enormous size of the stomach was probably a consequence of the intestinal obstruction rather than of the old ulcer, since the stomach had returned to its normal size within eleven days after the relief of obstruction, though the ulcer had not been touched.

1. Edwards, C. R.: Acute Intestinal Obstruction Due to Mesenteric Defects Requiring Massive Resection, J. A. M. A. **99**: 278 (July 23) 1932.

Cardiac Changes at Autopsy.—The microscopic cardiac and nervous changes are typical of both experimental and clinical vitamin B_1 deficiency. Those in the nerves were to be expected, for function was still greatly impaired in spite of the prolonged treatment. Those in the heart, however, were not anticipated, for the heart had been clinically normal since the end of the first month of thiamin therapy and no enlargement of its right side was found on gross examination.

Tuberculosis.—The caseous tuberculosis was an entirely unexpected observation. The patient's temperature had risen to 100 F. and the pulse rate to from 90 to 100 a minute a number of times during his period of hospitalization, but this was attributed to a reaction to the injections of liver extract or to cachexia. It is probable, however, that it was actually a manifestation of tuberculosis and that the tuberculosis was a consequence of the severe and prolonged undernutrition.

SUMMARY

Wet beriberi was a result of impaired absorption of vitamin B_1 as a consequence of a partial intestinal obstruction caused by a hernia in the mesentery, compli[illegible], a gastrojejunostomy and a[illegible]iagnosis was confirmed by the improvement of the patient under thiamin therapy and by autopsy.

30 North Michigan Avenue.

TULAREMIC INGUINAL BUBOES FOLLOWING TICK BITES

REPORT OF TWO CASES

JOSEPH G. PASTERNACK, M.D.

In Charge of the Pathologic Laboratory, U. S. Public Health Service, U. S. Marine Hospital

NEW ORLEANS

A bubo in one or both groins associated with fever is common. It is usually presumed to be of venereal origin. Frequently it occurs with pyogenic infections of the lower extremities, scrotum, perineum or pubis. The local lesion may be so small as to be overlooked or so slight as to be disregarded as the cause of the lymphadenitis. In certain localities bubonic plague must always be kept in mind.

Six cases of tularemic inguinal lymphadenitis following tick bite have appeared in the literature.[1] The two cases reported here illustrate that clinically the disease may be readily mistaken for any of the types of bubo mentioned.

CASE 1.—*History.*—A white man aged 23 was sent to the hospital May 8, 1937, from the CCC Camp at Bogalusa, La., because of fever and bilateral inguinal lymphadenitis. On admission his temperature was 39.7 C. (103.4 F.) and the pulse rate 120. He had some pain in both groins, which was augmented by walking. The distal superficial subinguinal nodes on the right side were enlarged and beginning to fuse. The mass measured 4 cm. in diameter. It was freely movable and tender

The Bureau of Entomology and Plant Quarantine, U. S. Department of Agriculture, furnished the photographs of the ticks.

1. These were reported by:

on pressure. The skin was not changed. The corresponding nodes on the left side were enlarged, discrete and tender. The largest measured 1.5 cm. in diameter.

For the past five days the patient's appetite had been poor and he was nauseated. He had vomited once. May 6 he had some pain in the right groin and found a tender "kernel." Later that day his left groin became painful. The venereal history

Fig. 1.—Tularemia: bilateral primary lesion.

was irrelevant. May 10 the patient was given the Frei test and reexamined. At this time a superficial ulcer 5 mm. in diameter covered by a thin black scab was found on the anteromedial aspect of the right leg just below the knee. A similar but apparently more recent ulcer was present on the lateral surface of the lower third of the thigh. Numerous scratches, excoriations and pinpoint pink papules were present on both legs. Inquiry about these lesions disclosed that the patient worked in underbrush where ticks were plentiful. At night he often removed as many as thirty ticks from his body. He first noticed the sore on his right leg when his groin became painful. He attributed this to scratching. When his attention was called to the ulcer on the thigh, he stated that it was "just a pimple several days ago."

Laboratory Data.—The leukocyte count was 8,500 per cubic millimeter, with a differential count of 69 per cent polymorphonuclears, 23 per cent lymphocytes, 6 per cent monocytes and 2 per cent eosinophils. The Wassermann, Kahn and Frei tests were negative. Smears and cultures of material from the ulcers and of the pus aspirated from the bubo in the right inguinal region showed no micro-organisms. Three guinea pigs inoculated subcutaneously with pus and brought to autopsy after nine, eighteen and twenty-seven days, respectively, showed no lesions.

The macroscopic tube agglutination test for Bacterium tularense with the patient's serum May 20 with a titer of 1:320 showed complete agglutination, June 3 with a titer of 1:640 complete agglutination, June 18 with a titer of 1:1,280 complete agglutination and with a titer of 1:2,560 partial agglutination, and June 26 with a titer of 1:2,560 complete agglutination and with a titer of 1:5,120 partial agglutination.

After I obtained this high and progressively rising agglutination titer, more pigs were inoculated with pus from the right bubo, again with negative results. When I spoke with Dr. Edward Francis about this case, he informed me that pus from suppurating lymph nodes infected with Bacterium tularense rarely yields the micro-organism on culture or produces infection in guinea pigs after the first month of illness.

Course.—The patient was decidedly ill. The fever continued for twenty-five days with morning remissions and evening rises in temperature to 38 or 39 C. (100.4 or 102.2 F.). The whole group of superficial inguinal nodes on both sides became involved and very painful. They formed huge doughy and fluctuant buboes. The skin was intensely red, edematous and adherent. Later it showed hemorrhagic and purplish discoloration and was very thin over the dome of the buboes. After three weeks of progressive suppuration the right bubo burst, discharging blood-streaked yellow creamy pus and sloughs of necrotic tissue. The bubo on the left side was aspirated and incised. Ugly, indolent wounds resulted. These healed after a number of weeks of energetic and varied treatment.

CASE 2.—*History.*—A white man aged 22 was sent to the hospital May 28, 1937, from the CCC camp at Springville, La., because of fever, chills, and inguinal lymphadenitis on the right side. On admission the temperature was 38.8 C. (101.8 F.) and the pulse rate 96. A subinguinal bubo 5 by 7 cm. in diameter was present on the right side. It was painful, tender on pressure and fluctuant in areas. The skin over the bubo was freely movable and not altered. The bubo had been developing for two weeks. In the past few days it had become painful, and the patient had chills, fever and a cough and ached all over. His head ached severely.

Long-standing dermatitis venenata due to poison oak was present over both legs. Small faint papules and excoriations were present over the legs, thighs and lower part of the abdomen. The patient stated that these were due to ticks, which he removed from his body daily after working in the woods

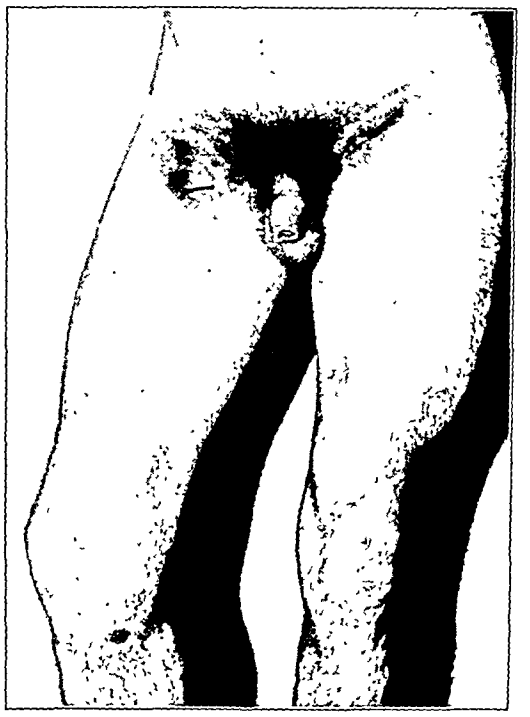

Fig. 2.—Bubonic tularemia, showing hemorrhagic discolorations of the skin over the buboes.

Three days previously he had removed a tick that was deeply embedded in the right scrotal fold, and he found one on the back of the scrotum after entering the hospital. The venereal history was irrelevant.

Laboratory Data.—The leukocyte count was 7,600 per cubic millimeter, with a differential count of 68 per cent polymorphonuclears, 27 per cent lymphocytes and 5 per cent monocytes. The Wassermann, Kahn and Frei tests were negative. The macroscopic tube agglutination test for Bacterium tularense

with the patient's serum May 29 with a titer of 1:640 showed complete agglutination, June 12 with a titer of 1:640 complete agglutination and with a titer of 1:1,280 partial agglutination, and June 29 with a titer of 1:1,280 complete agglutination.

Pathologic Study of the Excised Bubo.—The gross specimen consisted of six lymph nodes, of which the smaller were discrete and the larger partly matted together. The largest node measured 2.7 cm. in diameter. The nodes were soft and the

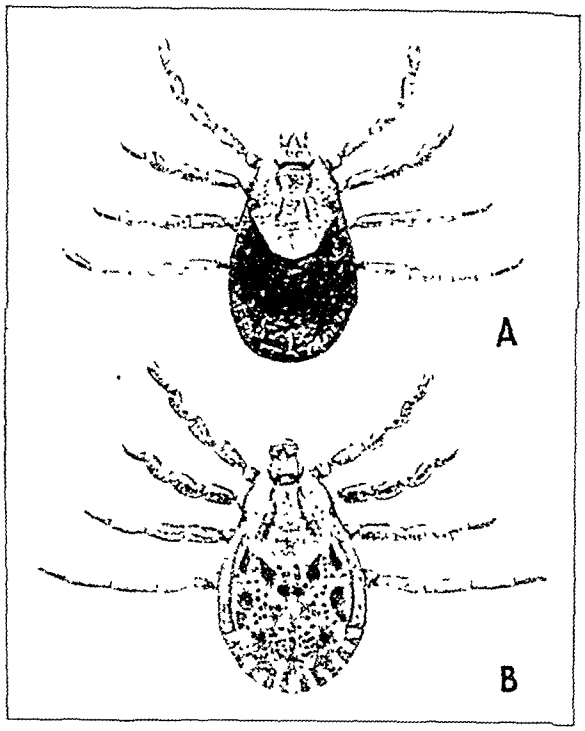

Fig. 3.—Dermacentor andersoni, *A*, female, *B*, male.

periadenoid tissue was hemorrhagic. On section the parenchyma was pink and mottled with miliary gray and red flecks.

Microscopically the lymphadenoid architecture was largely suppressed or obliterated. Large and small foci of early and advanced caseation containing aggregates of intact and degenerated polymorphonuclears were present in the large nodes. These were marginated by mantles of palisaded epithelioid cells. Occasional epithelioid granulomas and areas of diffuse epithelioid cell proliferation were present. Some of these showed beginning coagulation necrosis.

Infiltrations of polymorphonuclears and small numbers of monocytes and plasma cells were present throughout the parenchyma in all nodes. The sinuses were dilated and filled with serous exudate containing polymorphonuclears, lymphocytes and macrophages. Capillary vascularization of the parenchyma, irregular fibroblastic overgrowth, intense congestion and foci of hemorrhagic extravasation were present. An occasional focus of reticulum cell hyperplasia was seen. Fibrin was demonstrable in the margins of an occasional focus of beginning caseation.

The capsules and periadenoid tissue were overgrown by hemorrhagic vascular granulation tissue that showed focal abscessing and diffuse suppuration, dense lymphocyte infiltration and small numbers of monocytes and plasma cells. Fibrin was demonstrable in areas.

Many Langhans giant cells were present throughout the parenchyma, associated with and apart from the granulomas. Some were also present in the periadenoid granulation tissue.

The small and medium sized arteries showed diffuse edema and lymphocyte infiltration of their entire wall, various degrees of adventitial fibroblastic overgrowth and intimal proliferation with stenosis of the lumen.

Micro-organisms were not demonstrable in sections stained by the Gram, Gram-Weigert, buffered Romanowsky or Ziehl-Neelsen method or the Nile blue sulfate method advocated by Foshay.

Course.—The fever continued with morning remissions and evening elevations in temperature to 37.8 or 38.6 C. (100 or 101.4 F.) for over three weeks, until it was decided to excise the bubo. During this period it enlarged only slightly, but it became considerably softer and in areas markedly fluctuant. The skin was purplish and thin over the areas of fluctuation.

Within a week after the bubo was excised the patient became afebrile and began to improve. The wound healed slowly.

COMMENT

Francis [2] has pointed out that certain ticks are important agents in the transmission of tularemia. Wood ticks, Dermacentor andersoni, have caused the disease in fifty-three cases in Montana and the surrounding states. The dog tick, Dermacentor variabilis, has caused it in more than sixty-five cases in the Southern states, and in several cases it has been attributed to the Pacific Coast tick, Dermacentor occidentalis Neum.[3] Probably a number of other species of ticks play a part.

These ticks are biologic hosts for Bacterium tularense; that is, the infection acquired in one tick stage is passed on to the next, thus insuring perpetuation and spreading the disease among lower animals and thereby increasing the danger to man.

Ticks bite under the clothing or in the hairy areas of the body, where they may escape notice for long periods. The perineum and genitalia are favorite sites of tick bite. Francis [4] stated that he had had a dozen

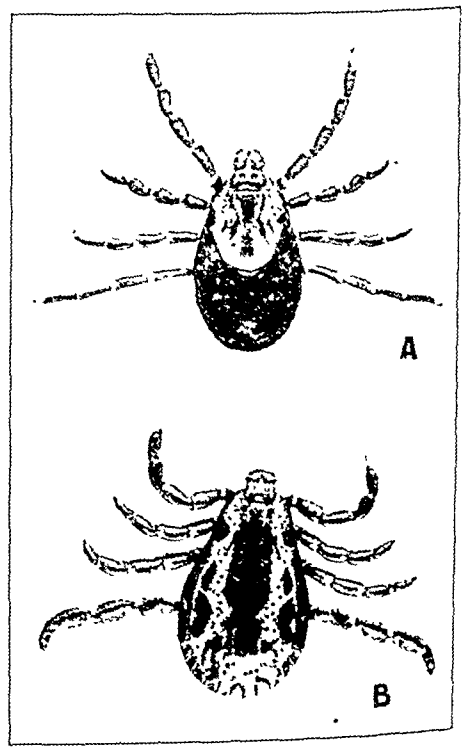

Fig. 4.—Dermacentor variabilis, *A*, female, *B*, male.

reports by letter of inguinal lymphadenitis that followed the bite of infected ticks in these areas. In several cases the adenitis was bilateral. In one of these the ulcer was present at the midline over the coccyx and in one over the pubis, in one there were multiple

3. Bishopp, F. C.: Ticks and the Role They Play in the Transmission of Diseases, Washington, D. C., Smithsonian Institution, Annual Report, 1935, pp. 389-406.
4. Francis, Edward: Personal communication to the author.

perineal ulcers and in one there was an ulcer on each leg, from which sites seed ticks had been removed several days previously.

The buboes in the two cases here reported occurred in May within three weeks of each other. The infection is seasonal, owing to the periodic prevalence and activity of the ticks and probably also to game laws.

From March to August are the months recorded for the onset in fifty-three cases of tularemia due to the wood tick, Dermacentor andersoni. These months correspond with the season of greatest activity of this species. This tick becomes infected in the larval or nymphal stage by feeding on infected rodents, and as an adult it infects man when it feeds on him. It has been found to feed in its various stages on a large variety of animals, the most important hosts of the immature stages being mice, ground squirrels and pine squirrels, while the adults feed mainly on larger wild and domestic animals.

From January to October are the months recorded for the onset in fifty-three cases of tularemia due to the dog tick, Dermacentor variabilis. The disease is widely distributed over the eastern two thirds of the United States and also occurs in California. In distribution therefore it almost occupies the portions of the United States not covered by the wood tick, Dermacentor andersoni. It is especially abundant along the coast from Cape Cod to the extreme southern part of Texas. It is troublesome as a parasite of dogs, horses, cattle, rabbits and man.

The wood tick, Dermacentor andersoni, and the American dog tick, Dermacentor variabilis, are related species. They resemble each other in general appearance, and their habits are similar. These ticks are especially abundant in wooded areas which are heavily overgrown with vines and underbrush. This condition not only gives the ticks protection but also protects the small wild rodents on which the young ticks feed. This at once suggests the desirability of cleaning out undergrowth and destroying small wild rodents in the vicinity of habitations and camps. In areas where hawks, owls and other predatory birds abound, removing the brush exposes the rodents to the attack of these birds.

It is stated that tick bites can be avoided by wearing proper clothing to exclude the ticks. Too much dependence, however, should not be placed on the exclusion of ticks, and the body should be thoroughly examined at frequent intervals when one is walking or working in tick-infested areas. Special attention should be given to the examination of the scalp and other hirsute areas of the body.

The number of ticks in a given area can be distinctly reduced by dipping infested dogs [3] and other livestock in a suitable tick-destroying solution or, in the case of pet dogs, by systematically picking the ticks from the animals to prevent the dropping of any engorged females. In removing ticks from dogs it should be borne in mind that the mere handling of an infected tick may cause infection, because Bacterium tularense can penetrate the unbroken skin. Hence the ticks should be picked off with forceps and the hands well washed with antiseptic solution.

Ticks removed from boys at the CCC camps in southern Louisiana from time to time were identified as the dog tick, Dermacentor variabilis, and the lone star tick, Amblyomma americana. A number of times ticks of both species were ground up and inoculated into guinea pigs. After weeks of observation the animals were well and showed no lesions at autopsy.

Diagnosis.—A bubo in the groin or regional lymphadenitis anywhere, when associated with fever, an ulcer of the skin or excoriations and scratches resulting from insect bites and coupled with a history of tick bite or fly bite (Chrysops discalis) should suggest tularemia. The agglutination of Bacterium tularense by the patient's serum in a dilution of 1 : 80 or higher is considered diagnostic of tularemia, provided there is no cross agglutination with Brucella abortus and Brucella melitensis.

SUMMARY

Bubonic tularemia of the groin is clinically similar to other types of inguinal bubo. The pus of suppurating tularemic buboes will rarely yield Bacterium tularense on culture or produce lesions in guinea pigs. Regional lymphadenitis associated with fever, an ulcer of the skin or excoriations and scratches resulting from insect bites, coupled with a history of tick bite or fly bite, is suggestive of tularemia. The agglutination of Bacterium tularense by the patient's serum in a dilution of 1 : 80 or higher is considered diagnostic.

STERILE MOTILE SPERMATOZOA, PROVED BY CLINICAL EXPERIMENTATION

FRANCES I. SEYMOUR, M.D.

NEW YORK

In May 1935 Mr. and Mrs. K. presented themselves with the problem of sterility. Both patients had been examined several times during their eleven years of married life. Neither husband nor wife had ever been operated on, nor had they at any time been ill other than with slight colds, and Mrs. K. with sinus trouble, which was a chronic condition, not severe enough to warrant operation. The last examination that they had undergone in an endeavor to determine the reason for their sterility occurred eight months before they presented themselves to me for reexamination.

Mr. K. was examined first and found to be in excellent health. A specimen of seminal fluid was obtained by withdrawal, the material being collected in a sterile pyrex beaker. The count revealed 94,000,000 spermatozoa per cubic centimeter of fluid, abnormal forms 3 per cent, motility index eighteen hours, fertility index (?) and pus absent. The spermatozoa were very active with markedly active use of the tail, movements of which were exceedingly rapid. With interference of viscid mucus obtained from the wife's cervical mucous plug, the spermatozoa, after becoming entangled, persisted for as much as an hour and a half to penetrate the obstruction. This, by the ordinary criterion that has been used to date, would have exonerated Mr. K. of any part in the sterility.

Mrs. K. was then examined. Her organs were freely movable on bimanual examination. There was no history of any pelvic abnormality; the menstrual cycle was normal; her weight and height were normal for her age, 38. Her mother did not cease menstruating until she was 49. The siblings in her family, two brothers and one sister, all had one or more children.

First reported at a sectional meeting of the Department of Urology, Brady Foundation, Cornell Medical Center.

A uterosalpingogram showed tubal patency and normal conformation of the uterus. The basal metabolic rate was plus 7. Wassermann reactions of the blood were negative in both husband and wife and the other blood work, including tests with follicle stimulating and luteinizing factors, gave negative results. Urinalysis showed no evidence of disorder; hemoglobin was 95 per cent in the Sahli test, the red blood cell count 4,750,000 and the white blood cell count 6,700. The differential count was normal. A series of sedimentation rates taken over a period of several weeks showed no marked vacillation. Mrs. K. was normal in every way. The Huhner test showed viable spermatozoa in the cervical canal.

Mr. K. is a professor in a nearby university and is constantly subjected to the grueling effects of university routine. He had been constantly in harness during the eleven years of his married life. Mrs. K. herself is a college graduate, highly trained, and assists her husband in his research work. Their life is principally taken up with intellectual matters, although they play some tennis.

Having found nothing that would lead one to suspect it as the cause of the sterility, neither of them showing any manifestation of endocrine dysfunction, both being of normal weight and normal habits, there was only one factor for consideration—the question of devitalization with a resultant lowered fertility index to such a degree that fertilization could not occur; that is, if such a condition actually exists. With this in mind, the patients were subjected by their local physician to biweekly and then weekly ultraviolet irradiations between November 1935 and May 1936. The diet was also drastically altered, with incorporation of a great deal of raw vegetables, such as salads and grated carrots and beets, all sorts of raw fruits, raw onions sliced and boiled onions. Meats and salads were spiced with an unusual amount of condiments and garlic. In addition, fish was eaten three times a week and considerable crustacea. Both the husband and the wife retired at an early hour, and afternoon rests became a habit. In addition there was a large daily dose of irradiated ergosterol, and, for Mr. K., weekly doses of testicular extract administered intragluteally, in increasing doses. However, with all this rest and therapy, by May nothing had happened. The patients then consented to a change of environment. Forthwith they went for their three months summer vacation to England, spending it in a rural suburb of London, relaxing completely and enjoying their vacation. However, October 1936 showed no improvement. There was only one significant deviation from the original examination in that the motility index had increased from eighteen hours to twenty-one hours.

It was decided at this time that, with the wife's consent, if a sufficient number of volunteers could be found, to cross inseminate them with Mr. K's spermatozoa to determine definitely whether the spermatozoa were fertile or not. Children by Mr. K. would have been highly desirable, since he has an intelligence quotient of 140, which throws him into the genius group. During the next year and a half we were able, with the consent of the women and their husbands, who were sterile, to start these inseminations on sixteen women. It was with their consent and knowledge that the spermatozoa of Mr. K. were used, although in many instances his nationality, religion and aptitude differed markedly from those of the sterile husband. In the next six months period spermatozoa were obtained from Mr. K. and the patients were artificially inseminated monthly. No pregnancies ensued.

At the end of this time it was decided, and consent was received from the participants in the experiment, that I should now use a donor whose fertility index was known. A man with an intelligence quotient of 120 was chosen—a man who was already the father of two children and whose wife practiced birth control. He was an eminent figure in his profession. His wife was also a college graduate, a highly intelligent person. They both realized the importance of the experiment and gave their full hearted cooperation. The viability index of the donor's sperm was thirty-one hours. Because of the uncertainty of the exact time of ovulation, it was thought best to have four inseminations each month on the sixth, tenth, twelfth and fourteenth day of each intermenstrual period, the first day of the period being considered as one. The frequency of these inseminations and the thirty-one hour viability index of the donor's spermatozoa gave reasonable assurance that the sperm would overlap the periods between inseminations. Another factor that came up later was that subjects 8, 13 and 15 would not take between these periods. After eleven months it was decided in these three cases to alter the days, which may be seen in the accompanying table.

The sixteen volunteers and the wife of Mr. K. were artificially inseminated over the next fourteen months,

when the rest of the volunteers, including Mrs. K., had become pregnant. The table shows the exact time at which each of the seventeen women became pregnant, the pregnancy being verified after the missing of the next monthly period and a positive Friedman reaction being obtained. The importance of this series is principally that motility of spermatozoa does not necessarily indicate fertility and that the retrieving of viable spermatozoa after coitus from the cervical canal does not exonerate the man as a cause of sterility.

The fertility index of spermatozoa may not be judged by conformity of the count per cubic centimeter, by ascertainable motility or by any of the other physical factors, diagnosable by ordinary microscopic examinations.

Clinical Notes, Suggestions and New Instruments

ROCKY MOUNTAIN SPOTTED FEVER WITH UNUSUAL FEATURES

E. HERBERT BAUERSFELD, M.D., WASHINGTON, D. C.

This is the report of a case of Rocky Mountain spotted fever, with observations made at autopsy, which is of unusual interest with regard to (1) mode of infection, (2) character and distribution of the rash, (3) lateness of appearance of the rash and (4) jaundice.

REPORT OF CASE

History.—M. F., aged 23, a white, married, unemployed American woman, admitted to Emergency Hospital June 7, 1938, complained of headache, chills and fever of four days' duration. She had been perfectly well until the afternoon of June 4, when she was taken with severe frontal headache and burning of the eyes. Shortly thereafter aching in her chest and legs and a slight cough developed. During the night she had a shaking chill followed by a rise in temperature and a drenching sweat. These symptoms continued, and the day before admission a decrease in auditory acuity, without earache, developed. The morning of admission she became nauseated and vomited and could not retain water. She stated that she had not been out of the city recently, had been drinking only city water and pasteurized milk and had eaten the usual cooked foods.

Her past and family histories were noncontributory.

It was later learned from the family that the patient had removed a tick from her husband about ten days prior to her illness. The husband, who was in good health, had recently hitch-hiked north from Florida.

Examination.—On physical examination the patient was well developed and fairly well nourished and was lying quietly in bed, alert and cooperative. The skin was hot and moist, and there was a suggestion of mottling over the abdomen (heat had been applied). Marked anterior flexion of the head elicited a slight pain down the back of the neck. There was moderate tenderness over the orbital rims; the scleras were clear; the nasal mucosa was injected; the lips were parched. The knee jerks were moderately hyperactive and there was an abortive ankle clonus. The Babinski and the Kernig sign were not present. The temperature was 103 F., respiratory rate 20, pulse rate 104 and blood pressure 115 systolic, 70 diastolic. The rest of the physical examination revealed no abnormalities.

Subsequent Course.—The patient continued to have a high fever, to have severe sweats and to grow progressively weaker. June 12, the ninth day of her illness, there were several petechiae in the conjunctivas and on the buttocks. June 13 there was a mottled maculopapular rash over the trunk, shoulders and upper parts of the thighs. By June 14 these areas had become petechial and were present on the upper arms. There was never any rash on the face, hands or feet. The lesions were discrete pinpoint to pinhead sized petechiae which did not fade on pressure. They were most numerous over the back and buttocks. On the day the petechiae were first seen, the patient showed decreased mental alertness, which progressed slowly to a stupor. On the morning of June 14 the scleras were icteric, and during the course of the day the skin became icteric. About 4 a. m., June 15, the patient became restless and anxious and went into coma, death following shortly thereafter.

The temperature ranged from 102 to 104 F. with occasional sudden drops to subnormal following severe sweats.

Examinations of the blood revealed: June 7: hemoglobin 90 per cent, erythrocytes 5,000,000 per cubic millimeter, leukocytes 7,550 per cubic millimeter with 98 per cent polymorphonuclears. June 13: hemoglobin 90 per cent, erythrocytes 4,470,000 per cubic millimeter, leukocytes 14,300 per cubic millimeter with 88 per cent polymorphonuclears. Agglutination of Bacillus proteus X 19 was positive in 1:80 concentration; of B. abortus, negative; of B. typhosus, negative and of B. paratyphosus A and B, negative. June 14: agglutination of B. proteus X 19 was reported negative by the United States Public Health Service. Spinal fluid June 7 and 12 showed 5 and 7 cells per cubic millimeter respectively. Blood culture, the Wassermann reaction, examination of the urine and x-ray examination of the chest were negative. June 14 guinea pigs were injected with the patient's whole blood and from them was isolated the virus of Rocky Mountain spotted fever. The virus conformed to the strain isolated from patients with the Eastern form of Rocky Mounain spotted fever.[1]

Autopsy.—This was performed by Drs. R. D. Lillie and T. L. Perrin of the United States Public Health Service.

Gross Appearance: The body was well developed. There was a general icterus of the skin, and numerous small petechial hemorrhages were present over the trunk, upper arms and thighs. The breasts appeared normal. On section there was a large hemorrhage in the left rectus muscle. The peritoneum was smooth and glistening. On the surface of the intestine were pinpoint sized hemorrhages. The visceral pleura was studded with pinhead sized hemorrhages over the left lower and right middle lobes of the lungs. There was a small amount of bloody fluid in the right pleural cavity. The visceral pericardium also showed numerous petechial hemorrhages.

The right ventricle of the heart was soft and distended with blood. The left ventricle was contracted. The valves were normal. There was marked congestion of both lower lobes of the lungs. The hilus nodes showed mild anthracosis. The spleen weighed 425 Gm. and was dark red and moist on section. The stomach contained some dark brown thin fluid, probably altered blood. The mucosa showed many pinpoint sized hemorrhages. The pancreas was normal. The liver was about normal in size. On section there was a slight yellow and brown lobular mottling. The gallbladder was moderately distended with very dark bile that could not be expressed into the duodenum. A probe could not be passed without making a false passage. No stones were found. The adrenals were normal. The size of the kidneys was normal. Many petechial hemorrhages were present in the pelvic mucosa. There was a small amount of blood in the uterine cavity. Several small hard white nodular tumors from 3 to 5 mm. in diameter were found in the ovaries. The bladder was distended with urine, which gave a yellow foam on shaking. The mucosa was studded with petechial hemorrhages. The mucosa of the intestine showed many petechial hemorrhages. The fecal material in the colon was clay colored.

Gross examination revealed: (1) petechial eruptions in the skin, in the serous membranes including the visceral pleura, pericardium and peritoneum and in the mucosa of the gastrointestinal tract, renal pelves and bladder; (2) icterus; (3) splenomegaly, and (4) congestion and edema of the lungs.

Microscopic Appearance: In the epicardium and myocardium and beneath the endocardium there were many small focal hemorrhages; also areas of vascular endothelial swelling, adventitial proliferation of fibroblasts and moderate perivascular

A BEDSIDE METHOD FOR DETECTING DEXTROSE IN THE URINE

HERMAN L. JACOBIUS, NEW YORK

Benedict's test for dextrose in the urine can be simplified for practical bedside purposes by using the solution dried on a wad of asbestos and applied to the end of a wooden applicator.

Asbestos paper soaked in Benedict's solution is molded onto the end of a wooden applicator, again thoroughly moistened with the solution and then allowed to dry in air. The test is then carried out by dipping the end of the applicator into the urine or by merely allowing two drops of urine to fall on the end of the asbestos and then gently heating the urine-moistened asbestos over a noncharring flame (Bunsen, stove range, alcohol lamp). A yellow color develops, the intensity of which depends on the concentration of dextrose in the specimen.

A rapid method using asbestos paper and bismuth salts and requiring heat for completion has been devised by Mr. Harold Wright [1] of Forest Hills, N. Y., but this has the disadvantage of being rather cumbersome to make up. Recently the Denver Chemical Manufacturing Company has put out its "galatest" for rapid detection of dextrose in urine with the salts of bismuth. The latter test seems to be rapid and accurate and has the advantage of not requiring heat for its completion but the disadvantage of using caustic materials.[2]

In the manufacture of my asbestos applicators I have used standard Johns-Manville asbestos paper one thirty-second inch thick. The paper is cut into strips and soaked in Benedict's solution for twenty-four hours. At the end of this time pieces of the soaked paper about the size of an almond are molded on the end of wooden applicators, again moistened in the Benedict's solution and allowed to dry in air. Applicators thus made may be stored at least three or four months without loss of their sensitivity. In carrying out the test it is necessary to dip the asbestos tip of the applicator into the specimen of urine or apply two drops of urine, so that on the completion of the test a yellow line of demarcation is noted between the moistened and the unmoistened portions of the applicator if the test is positive.

Any source of heat that does not deposit soot on the surface of the asbestos may be used to carry out the test. It is important to avoid the direct heat of the flame to prevent charring.

The applicability and sensitivity of the method were tested by examining graded concentrations of dextrose in normal urine

Association of Color Gradations with Concentrations of Dextrose

Concentration	Color
3 per cent or more	Orange
From 1 to 3 per cent	Canary yellow
From 0.5 to 1 per cent	Greenish yellow
From 0.1 to 0.5 per cent	Faint yellow on a green background
0.07 per cent	No change

ranging from 0.6 to 5 per cent. In these experiments definite color gradations were associated with the concentrations of the dextrose given in the accompanying table.

The cost of the materials required for the test is minimal. The asbestos paper costs 10 cents a pound and the wooden applicators 10 cents a hundred. I have calculated the cost of a single asbestos applicator to be 0.4 cent.

Tests of diabetic urine of known dextrose concentration, determined by more elaborate quantitative methods, showed an agreement with the results obtained with the asbestos applicators close enough for ordinary clinical purposes.

At no time did various specimens of normal urine give a yellow color with the asbestos test. Approximately 100 samples of normal urine were tested, and none gave a false positive reaction. No other pathologic constituents of the urine, viz., blood and bile, interfere with the results of the test.

The applicators are as convenient to carry about as are tongue depressors, and both the physician and the patient are able by this rapid, inexpensive test to determine the approximate concentration of sugar in the urine within one minute.

Cooperation was given the author by Dr. Eugene F. Du Bois and Dr. Gustave I. Steffen.

From the New York Hospital and Department of Medicine, Cornell University Medical College.

RADON SEEDS

PHYSICAL CONSIDERATIONS: DO THEY LEAK AND DO THEY IRRITATE TISSUES?

EDITH H. QUIMBY, M.A.
NEW YORK
AND
ARTHUR U. DESJARDINS, M.D.
ROCHESTER, MINN.

PHYSICAL CONSIDERATIONS

A short time after radium was discovered, it was found that objects in the neighborhood of open radium preparations acquired a radioactivity of their own. This activity was very short lived if the object was removed from the vicinity of the radium but could be renewed at will by bringing it back.

This mysterious phenomenon is readily explained when the sequence of radioactive changes is known. Radium itself is a metal, belonging to the same chemical group as barium and calcium. The nucleus of the atom is, however, unstable, and at some (entirely unpredictable) time it suddenly ejects a portion of itself. This portion, which is called an alpha ray or alpha particle, is exactly like the nucleus of a helium atom. In any given quantity of radium, every instant a certain percentage of all the atoms present undergo this transformation, the rest remaining completely unchanged. The apparent result of this is that the quantity of radium present gradually decreases. But it must be remembered that this gradual decrease is the result of a series of sudden transformations.

When a radium atom has ejected an alpha particle, what is left behind is no longer radium but a new element, radon. This element is a gas, belonging to the same chemical family as helium. Being a gas, it need not remain with the radium atoms but can float away, remain for some time in the air or settle on some object. Radon is itself unstable. At some (also unpredictable) time after its formation, the radon atom expels an alpha particle. The residual atom is known as radium A and is another metal, belonging to the chemical group of selenium and tellurium. These metallic atoms settle on any nearby object, forming a film so thin as to be invisible. They, in turn, eject alpha particles, and this alpha radiation naturally appears to come from the object on which the radium A has settled; this is the "acquired radioactivity" mentioned in the first paragraph. When radium A disintegrates, its product is

From the Memorial Hospital, New York (Edith H. Quimby), and the Mayo Clinic, Rochester, Minn. (Dr. Desjardins).

Special report prepared for the Council on Physical Therapy of the American Medical Association partly as a result of a special investigation to determine the question of leakage.

another solid, as are all the subsequent ones. This element, called radium B, belongs to the same chemical family as lead.

Radium B disintegrates in a different manner from the preceding elements; it ejects an electron, known as a beta ray, or beta particle. Accompanying this particle are rays of the same sort as roentgen rays; these are called gamma rays. The next substance, radium C, emits all three types of rays in its disintegration.

It is evident that these radioactive substances are arranged in a family, or series. As a matter of fact, three such series are known, but only this one is of much practical importance in radiation therapy. This is called the uranium series, since its first member is uranium. Radium is the seventh member; for the present purpose its ancestors are of little significance. The part of the series which has been discussed, and which is all that is of interest in radiotherapy, may be condensed in a diagram as in figure 1.

Each member of the series is a true chemical element. It enters into combinations with other elements in accordance with the chemical group to which it belongs. Every one has its own characteristic manner and rate of disintegration, which for any given substance is always the same and is not influenced either by the chemical combination in which it exists or by the action of physical agents (such as heat and cold).[1]

The three types of rays differ greatly in their penetrating powers. The alpha rays, which are helium nuclei traveling at high speeds, cannot penetrate to any appreciable distance in solid matter; in fact, they are all stopped by an ordinary sheet of paper. Evidently they may be ignored in radiation therapy. The beta rays, electrons traveling at considerably greater speeds than the alpha rays, are more penetrating. Many of them will pass through several millimeters of tissue; they are all stopped by 2 mm. of brass or 0.5 mm. of platinum or gold. They are of use in therapy only for extremely superficial conditions. The gamma rays are, like roentgen rays, electromagnetic radiations traveling with the speed of light, and they are very penetrating. Some of them can pass through several inches of lead. They are the ones which must be used to affect cells at distances of more than a few millimeters in tissue.

The problem of radiation therapy is to deliver a sufficient quantity of radiation to the cells it is desired to affect, without at the same time producing undesirable effects on other tissues. In radium therapy this implies an adequate amount of gamma radiation.

As stated, no gamma radiation is produced by radium itself or by its immediate descendants; the gamma rays come from radium B and radium C. If, however, the radium is in a sealed container, its decomposition products will accumulate there with it and their radiation can be attributed to it. If, on the other hand, the arrangement is such that the radon atoms can drift away (or be pulled away) as fast as they are formed, the radium would be seen to emit only alpha rays. Similarly, if radon is sealed into a tube so that its descendants must also remain there, their radiation can be attributed to it. It is evident that, as far as the available radiation is concerned, it makes no difference which is used; in either case it is the later members of the series which actually produce the useful rays.

Radium loses its activity very slowly. Of any given amount, half will have disintegrated in 1,590 years, or only a small fraction of 1 per cent a year. Of radon, however, half will have disintegrated in 3.82 days (16.6 per cent in one day). Of the half remaining, one half will disintegrate in another 3.82 days; of the amount now remaining (one fourth of the original amount) half will be lost in another equal period, and so on. It is evident that, whereas a supply of radium would be practically constant during one man's lifetime, a supply of radon would vanish very rapidly unless it was replenished. If, however, the radium could be put in a safe and allowed to remain there, and the radon drawn off every day, a continuous supply of active material would be assured. The radium would not be in danger of loss or theft; the loss of some radon would not be serious because the next day a fresh supply would be available.

There are other advantages in using radon. An amount of radium is specified in terms of grams (or milligrams) of radium element present in any given preparation. The amount of radon having the same gamma ray activity (actually whose descendants are the same) as 1 Gm. of radium is called 1 curie; the amount corresponding to 1 mg. of radium is 1 millicurie. One millicurie of radon can be compressed into much less space than 1 mg. of radium, so that radon sources can be made much smaller than radium ones of the same strength. Moreover, if the radon is removed each day

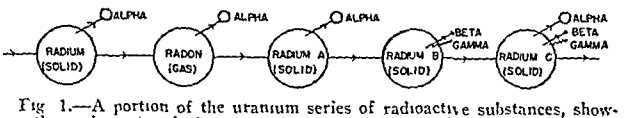

Fig. 1.—A portion of the uranium series of radioactive substances, showing those elements which are important in radiation therapy.

from the radium source it can be put into tubes or containers of various sizes and shapes, so that a variety is always on hand.

As soon as a radon source is separated from its parent radium it begins to deteriorate, as already stated, at the rate of 16.6 per cent daily. The day a source is prepared, its strength is measured by comparing its gamma ray activity with that of a known amount of radium sealed in a permanent tube.[2] Thereafter its strength can be calculated at any time, since its hourly and daily rate of loss is known. Practical tables have been developed for this purpose. The effective lifetime of a source depends on its initial strength and on the purposes for which it is used.

In practice, the actual separation of radon from radium requires the use of complicated physical apparatus and the services of a trained technician. The appearance of such an apparatus is shown in figure 2. The radium, in the form of a solution of radium chloride, is kept in the safe. Glass tubes connect the flasks containing the solution with the apparatus; a vacuum is maintained in the whole system. At the time of the collection of the radon, by manipulating the vacuum pumps and the mercury in the various flasks the operator forces the radon gas which has accumulated above and in the radium solution into the part of the apparatus marked *A*, where it is purified. The impurities consist mainly of water vapor, hydrogen and oxygen, all of which have come from the solution. When they have been removed, the radon remaining occupies an extremely small volume. It is then pumped

1 For a detailed discussion of radioactivity, radioactive series and radioactive constants the reader is referred to standard works on the subject. Among these are

Glasser, Otto, editor. The Science of Radiology, Springfield, Ill., Charles C. Thomas, Publisher, 1933.

2 A description of such measurements would be out of place in the present report. They are carried out by means of special electrical instruments developed for the purpose, which must be available in any institution where radon sources are prepared.

to the region above the stopcock marked *B*. At this point the metal or glass containers to be used will have been previously sealed on, and the radon can be forced into them. The filled containers can then be removed, measured and prepared for therapeutic use.

When the radon is enclosed in the usual type of thin glass tube, the rays emitted from the tube consist of about 96.5 per cent beta and 3.5 per cent gamma. If this tube is embedded in tissue, 97 per cent of the total radiation emitted is absorbed in the centimeter of tissue immediately surrounding it. Only 3 per cent of the initial radiation penetrates 1 cm. of tissue; this is mainly gamma radiation.

If the glass tube is enclosed in 0.5 mm. of platinum, all of the beta and some of the gamma rays will be absorbed in this metal; the radiation emitted from the surface of the platinum tube will be only 2.77 per cent of that from the glass tube, but it is all gamma radiation.

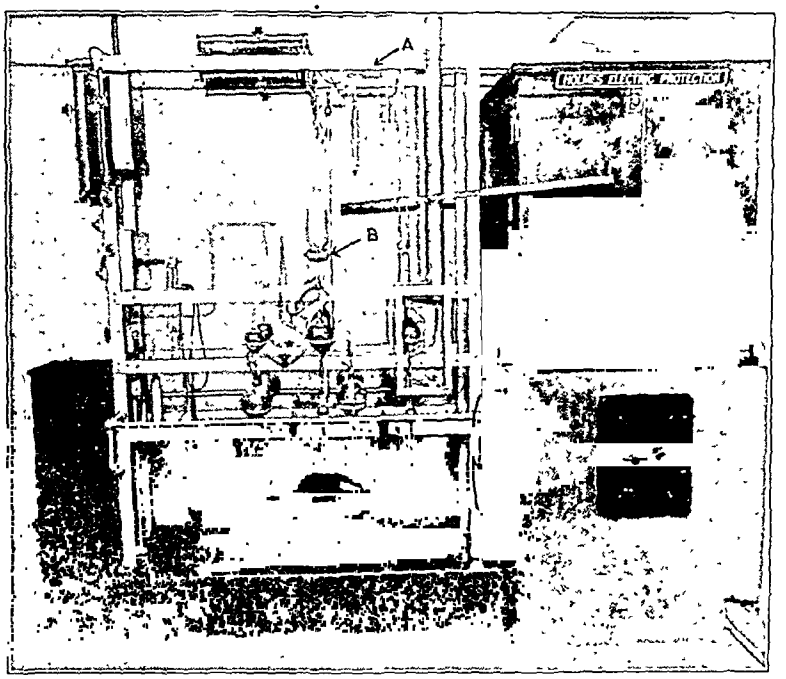

Fig. 2.—Apparatus used at Memorial Hospital for the separation of radon from radium.

Of this, 6 per cent is absorbed in the centimeter of tissue immediately surrounding the tube; 94 per cent penetrates to more distant cells (in contrast to only 3 per cent for the glass tube). Ninety-four per cent of 2.77 is 2.62. In other words, when the half millimeter platinum tube is used, 2.62 per cent of the initial radiation reaches cells at more than a centimeter distance, as compared with 3 per cent for the glass tube alone. But in the latter case (glass) the tissue surrounding the tube has to absorb the other 97 per cent, whereas in the former (platinum) they were absorbed largely in the tube itself.

Evidently with the glass tube, in order to deliver an adequate dose at a distance of a centimeter in tissue, an excessive dose must be administered to the region close about the tube. When the metal is employed it absorbs the oversupply of beta rays, and the nearby tissues do not suffer so greatly. This process of removing undesirable radiation by the use of metal covers for radium (or radon) sources is called filtration. It is a factor deserving of great consideration when radioactive sources are implanted directly into the tissues (interstitial irradiation).

A factor of even greater importance is the distance from the source.[3] The intensity of radiation falls off very sharply at a short distance from the tube because of the spreading of the rays, the well known inverse square law. The extreme effectiveness of this law in interstitial irradiation may readily be illustrated. Consider an implant[3] so small as to be practically a point source of radiation; the rays are emitted from it in all directions. All of them except those absorbed in the first 5 mm. of tissue pass through the surface of a sphere at this distance (5 mm.) from the source. The area of this sphere is 3.14 sq. cm. ($4 \pi r^2$). All the rays which pass through this sphere, except those absorbed in the next 5 mm. of tissue, must also pass through a spherical surface at 1 cm. from the source. The area of this outer sphere is 12.56 sq. cm., which is just four times that of the inner one. The same amount of radiation must hence be spread out over four times the area, so that any particular cell or group of cells at the larger distance receives only one fourth as much radiation as it would at the smaller.[4] At 1.5 cm. it would receive only one ninth as much. It is apparent that cells at any great distance from an implant will receive a very much smaller dose of radiation than those close to it.

This decrease in intensity by virtue of the inverse square law is completely independent of the absorption of radiation by the tissue referred to. The statement that 94 per cent of the radiation from a half millimeter platinum tube penetrates to a distance of a centimeter in tissue must not be interpreted as meaning that the intensity at 1 cm. distance is 94 per cent of that at the surface of the implant. This 94 per cent is spread out so that it covers an area many times the area covered by the total radiation at the tube surface, so that the actual intensity (radiation per unit area) at 1 cm. is an extremely small fraction of that at the surface of the tube. It is evident that for filtered radiation the effect of distance on the intensity is much more important than that of absorption in the tissue. These effects of filtration and distance will be referred to later, in connection with the practical application of radon in interstitial therapy.

The first actual treatment of a tumor by the insertion of radium directly into it appears to have been done by Dr. Robert Abbé in New York in 1905. He made a surgical incision into an exophthalmic goiter, placed the tube in it, and left it for twenty-four hours. Following his report of this case, others used the method for some time. Their applicators were all bulky; little effort had been made to limit their size. Stevenson and Joly took a great step forward when they utilized radon (at that time called radium emanation). This they could introduce into very fine glass tubes, which could in turn be placed in fine hollow steel needles. These were inserted into the mass to be treated and

3. The "source" of radiation is its point of origin; in the case of radioactive substances it is the actual radium or radon. It is sometimes customary to refer to the tube containing this material as the source. When this is done, it must be remembered that only the portion of the tube or needle which actually contains radioactive material (the "active portion" or "active length") can thus be considered. An "implant," as considered in this article, is any tube, needle, cell or other container of radium or radon inserted directly into the tissues. The method of inserting the gold seeds considered in the present report is outlined later.

4. Actually they receive less than one fourth, because of the decrease due to absorption in the intervening tissue.

were removed after a suitable time. The advantages of these needles were so apparent that efforts were immediately directed toward reducing the size of the radium containers, and shortly radium needles were available which were quite small.

Meantime, Duane had suggested that small amounts of radon might be put into tiny glass tubes, and these inserted directly into the tissues by means of a trocar and cannula and left there permanently. Since the radon would disintegrate at the rate of about 16 per cent of the amount present every day, at the end of a month less than 1 per cent of the initial amount would remain. The glass tubes would be sterile and harmless and need no further attention. This idea appealed to Janeway, who wished to test it at the Memorial Hospital. Failla accordingly developed a method for making the glass capillaries very fine and small. Janeway called these tiny implants "bare tubes" and used them successfully over a period of several years.

The method had many advantages over the use of the clumsier removable implants, but it had one great disadvantage. An intense necrosis developed around each implant. This was sometimes responsible for great pain and for the breakdown and slough of the tissues. The foregoing discussion of filtration makes it evident that this was mainly due to the effect of the beta rays and that if they could be removed the situation should be improved.

As a matter of fact, Regaud and his associates, using small platinum needles thick enough to remove the beta rays, and with small radium content, so that prolonged irradiation was necessary, were obtaining good final results with little or no necrosis. It was apparent that, if a filter could be used with the permanent implants, much of the difficulty due to the necrosis could be eliminated.

Various schemes were tried to accomplish this purpose. Heublein attempted to surround each tube, as it was implanted, with a suitable thickness of bismuth paste, using the same needle for the radon and the paste. Preliminary results were unsatisfactory because the distribution of the paste was irregular. The work was abandoned because of the development of more satisfactory methods.

Failla had tried making bare tubes of lead glass, which would absorb more of the beta rays than ordinary glass. However, the thickness of the material required to remove most of the beta rays was so great as to make the tubes unsatisfactory for interstitial use. He accordingly turned his attention to the problem of a metallic tube. The metal should be one with a very high absorbing power, so that the tube walls could be thin. Practically this limited the choice to platinum, gold and iridium. Of these, gold is the least expensive and it has an additional advantage which actually makes its use practical. Pure gold is quite soft, so that if a tube of fine bore is pinched together with a blunt pair of pliers a gas-tight seal will be formed. The problem of sealing gold tubing to the glass radon collecting apparatus had to be solved, but a simple means for doing this was developed.

Implants of this type should be as small as possible. As already stated, a wall thickness of 0.5 mm. of gold is required to remove all the beta rays. To use this would result in an implant having about three times the diameter of the glass seeds. It was felt that a compromise would be desirable whereby the diameter could be kept smaller but a favorable percentage of the beta rays removed. A filter of 0.2 mm. of gold transmits 3.72 per cent of the bare tube radiation; of this about a fourth is beta radiation. One of 0.3 mm. gold transmits 3.16 per cent of the original; of this less than one tenth is beta. As stated previously, one of 0.5 mm. gold transmits 2.77 per cent of the original radiation, all gamma. After traversing 1 cm. of tissue, in this last beam there will be 2.62 per cent of the original radiation; in those filtered by 0.2 and 0.3 mm. of gold there will remain 2.80 and 2.73 per cent respectively. This means that, in the case of the radiation filtered by 0.2 mm. of gold, 25 per cent has been absorbed in the first centimeter of tissue, of that filtered by 0.3 mm. 14 per cent, and of that filtered by 0.5 mm. 6 per cent. These data are presented in table 1. From the point of view of these figures, the 0.3 mm. gold filter seemed a reasonable and satisfactory compromise. However, various physical, chemical and biologic experiments were performed with gold tubes having walls of 0.2 and 0.3 mm. in order to ascertain which gave the better combination of small size and reasonable filtration.

The first pure gold tubing used had a bore of 0.2 mm., but this was found to be larger than necessary. A bore of 0.1 mm. was practical, but in general a bore of 0.15 mm. seems most satisfactory. Hence tubes of 0.3 mm. wall and 0.15 mm. bore, making a total outside diameter of 0.75 mm., were finally adopted.

TABLE 1.—*Data Regarding Gold Filters*

Mm. Gold Filter	Percentage of Total Radiation	Percentage Beta	Percentage Gamma	Percentage of Total Radiation Passing Through 1 Cm.	Percentage of Total Radiation Absorbed in First Centimeter
0	100	96.5	3.5	3.14	97
0.2	3.72	22.5	77.5	2.80	25
0.3	3.16	8.8	91.2	2.73	14
0.5	2.77	0	100	2.62	6

A detailed discussion of the extensive experimental work would be out of place here; the interested reader is referred to Failla's original paper.[5]

The "gold seeds" as actually used are about 4 mm. long and contain from 0.5 to 3.0 millicuries of radon. They can be sterilized by boiling. In no case has any significant leakage of radon been detected after boiling for one hour. The possibility of a seal's opening under pressure from the needle as the seed was inserted was tested by injecting a number of them into pieces of tough meat and later recovering them. During this process they were deliberately handled much more roughly than they would be in therapeutic practice. When they were remeasured after recovery, and subsequently, no evidence of a seal's opening was obtained in any case.

It seemed possible that the chisel-like ends of the seeds might be objectionable. Various schemes have been tried for rounding the ends, not one of which has proved entirely satisfactory. Meantime, repeated roentgenograms of some patients, made over periods of years, have demonstrated that the seeds remain in place. At the Memorial Hospital, where the method has been used for more than twelve years, there has been no complaint of trauma from these edges.

The question of the disposition of the implants, permanent or removable, seeds or needles, in the tissues is extremely important. The variations in intensity of radiation due to the inverse square law have already

5. Failla, Gioacchino: The Development of Filtered Radon Implants, Am. J. Roentgenol. 16: 507-525 (Dec.) 1926.

been explained. Because of these variations, the distribution of radiation throughout an implanted mass of tissue must evidently be very uneven. It seems advisable to present some numerical data on this point. In table 2 are shown intensities of radiation at different distances from a point source in percentages of the intensity at a distance of 2 mm. from it. In table 3 are shown the variations in intensity at a point half way between two implants as the distance between

TABLE 2.—*Effect of Distance on Intensity of Radiation*

* Neglecting absorption in tissue.

them is increased. In both of these tables the absorption of the radiation in tissue is neglected; it would act to make all the values somewhat less. Gold seeds are so small that point source data apply fairly closely. For longer implants, the inverse square law is not strictly applicable; the variations with distance are not so great, although still large. Data for making the proper allowances for the effect of length are available in the literature.[6]

From the data of tables 2 and 3 it is evident that, if the implants are too widely spread, either regions between them will be underirradiated or regions close around them will be overtreated. At best, the distribution of radiation is bound to be uneven. It must be considered that the reaction of cells which receive the least dose is the most important. If these react satisfactorily, others receiving greater doses should also. Hence, in planning treatment of a tumor, the amount of radiation required to deliver at least a certain minimum dose throughout should be ascertained. In order to implant a lesion properly, its dimensions must be known as accurately as possible and an adequate number of seeds or needles prepared so that the desired minimum dose can be delivered as uniformly as possible. Certain rules must be followed in placing the radioactive sources within the lesion.

TABLE 3.—*Effect of Spacing of Implants on Dosage in Intervening Tissue*

* Assuming 100 per cent as the amount delivered at 2 mm. from a single point source, as in table 2.

A great deal of work has been done on proper methods of delivering desired doses in interstitial therapy (implantation of radon). It is not felt that data of this kind should be incorporated in a report such as the present one. The reader who wishes such information is referred to the original papers.[6] However, it cannot be too strongly emphasized that a knowledge of the size of the mass and the amount of radon (or radium) required is only the beginning of adequate treatment. Proper training in the technic of implantation is essential, as well as experience in the method. Most important of all is sound clinical judgment in determining the method of choice in any given instance.

These points may be illustrated by the diagram of figure 3. In both parts the heavy black line represents the outlines of a lesion 2 cm. in diameter; it has been ascertained that it can be correctly treated with four seeds placed 1 cm. apart as shown in the left hand figure. (The entire diagram is drawn to the same scale.) A margin of safety all around the lesion receives adequate dosage. In the right hand figure, three of the seeds have been displaced, each by less than 0.25 cm. Now a part of the actual lesion is outside the 100 per cent zone, and the margin of safety is meaningless. It is obvious that neither the size of the mass nor the positions of the implants can be determined with any such degree of accuracy as is supposed in the first diagram. Accordingly, it is necessary for the clinician to decide how much leeway he must leave in deciding his dose, and how much irregularity he may permit himself in implanting his sources, and then to be sure that he does not overstep the limits he has set.

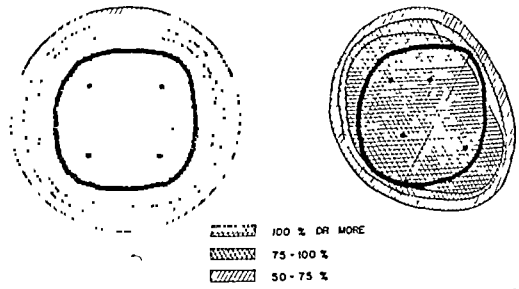

Fig. 3.—Diagram to illustrate the importance of accurate placing of sources in interstitial radiation therapy.

REPORT OF INVESTIGATION ON LEAKAGE

For many years, as far as supervision by any of the councils of the American Medical Association is concerned, all matters pertaining to and all advertising of radium and preparations of radium in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION came within the purview of the Council on Pharmacy and Chemistry. The Council on Physical Therapy had not then been organized. It was during this period that therapeutic radiologists became aware that the use, by implantation into tumors or tissues, of sealed segments of capillary glass tubing containing varying amounts of radon had the serious disadvantage of causing a zone of tissue in the immediate vicinity of these glass-radon implants[7] to undergo necrosis and, as a consequence, of inducing more or less severe pain in any region treated by this method. The necrosis and the resulting pain were due to the insufficient filtration, which allowed all the gamma rays and a considerable proportion of the beta rays as well to escape from the glass containers. As the beta rays are readily absorbed, they exerted their effect indiscriminately on all the cells surrounding the glass seeds to a depth of several millimeters and thus accounted for the necrosis and the pain. In order to obviate this difficulty it was essential to filter the radon sufficiently to eliminate all the beta rays and perhaps also the least penetrating fraction of the gamma

Radiol. **11**: 252-266 (April), and 313-340 (May) 1938.

7. Because of their small size, these sealed segments of capillary glass tubing containing radon had long been generally known as "radon seeds."

rays. Experiments carried out by Lacassagne [8] in 1921 showed that, when plain glass seeds containing radon were embedded in a mass of tissue, the effect was to cause all the tissues surrounding each seed to undergo necrosis for a distance of from 1 to 8 mm. from the seeds. Moreover, for seeds containing from 0.7 to 26 millicuries or more of radon the final diameter of this zone of necrosis was proportional to the amount (or strength) of radon in each seed. When, instead of glass, the seeds were made of segments of fine platinum tubing with a wall 0.15, 0.30, 0.40 or 1 mm. thick and contained the same quantity (or strength) of radon, the thickness of the resulting zone of necrosis diminished as the thickness (and therefore the filtering value) of the platinum increased. Thus platinum seeds with a wall thickness of 1 mm. and containing 10 millicuries of radon did not cause necrosis, while with similar seeds containing 20 millicuries of radon the resulting zone of necrosis was 2 mm. thick, and with seeds containing 34 millicuries of radon the zone of necrosis was 5 mm thick. The results subsequently obtained by Cutler [9] and by Quimby and Stewart [10] corroborated those of Lacassagne on the whole, although they showed slight variations in detail which related mainly to reparative changes occurring later in the zone of tissue affected by irradiation under the conditions of the experiments. According to these workers the diameter of the necrotic zone produced by radon seeds embedded in tissue is not proportional to the quantity of radon in the seeds.

The idea of making radon seeds of metal such as platinum in order to filter out the beta rays and some of the gamma rays had occurred to Regaud at least as early as May 1919, because at that time he applied for and obtained from the French government a patent to cover and protect a method of making radon seeds by pinching off and clipping short segments of fine platinum capillary tubing into which a certain quantity of radon had been pumped. With two exceptions, this is essentially the method which has been employed almost universally ever since. One exception refers to a method devised and patented by an American company, whereby sealed glass seeds are inserted into a small capsule of platinum with smoothly rounded ends. The advantages claimed for this method of preparing metal seeds are that the possibility of leakage is obviated and that the smooth ends of the seeds avoid possible mechanical irritation to tissues which, theoretically at least, might be caused by seeds with ends of metal. The other exception is that, in this and certain other countries, gold tubing has generally been used instead of platinum tubing.

At about this time and as a result of competition between two commercial concerns in this field, a considerable advertising controversy arose and was waged for some time. The company which had devised and patented a method of preparing radon seeds by first sealing the radon in segments of capillary glass tubing which were then placed in small platinum capsules with smoothly rounded ends naturally made the most of the theoretical rather than practical advantages of this method. The implications were that (1) radon seeds prepared by pinching off and clipping segments of metal tubing could never be free from the possibility of leakage and that their use, therefore, must be fraught with uncertainty as to dosage unless repeated physical measurements of their radon content should be made, and that (2) the pinching off method must necessarily result in ragged ends, which must irritate tissues into which seeds thus prepared should be implanted, whereas the smoothly rounded ends of radon seeds prepared by the patented method employed by this company could not possibly irritate the tissues. The first argument will not be considered now but will be dealt with later. As for the second contention, that the "pinching off" method leaves jagged ends which must irritate the tissues, this can be easily shown to be at least an exaggeration which could mislead only persons who are not familiar with the details and methods of radium therapy.

TABLE 4.—*Results of Measurements of "Pinched Off" Gold Seeds from One Company*

There was no marked leakage from the seeds from the other company

When radon, either in bare glass "seeds" or in metal "seeds," is embedded in the living tissues of a patient, the first step usually is to inject a local anesthetic if the lesion to be treated is small, or to put the patient under the influence of a general anesthetic if the lesion is large. Then, after the physical pattern according to which the units of radon ("seeds") are to be distributed and arranged within and around the lesion has been decided on, a number of small slit incisions are made in the skin or, such incisions being dispensed with, a

8 Lacassagne, Antoine Recherches experimentales sur l'action des rayonnements B et r du radium agissant dans les tissus par radiopuncture, J de radiol et d'electrol 5: 160 173 (April) 1921.

long hollow needle of large bore, similar to a lumbar puncture needle, or a fine trocar, is inserted into one of the planes of the lesion. A glass or metal seed containing a certain quantity of radon is then placed in the outer end of the lumen of the needle and is allowed to slide down the lumen until it reaches the far end of the needle lying within the lesion. Then a fine metal rod with a diameter corresponding to the bore of the needle or trocar is pushed down the lumen until it comes in contact with the seed. The next move is the crucial step as far as mechanical irritation of tissue by the seed is concerned. If from this point the seed were forced out of the needle by pressure on the mandrel, as is somtimes done, this maneuver might give a semblance of justice to the argument that seeds prepared by the "pinching and clipping" method irritate the tissues in which they are embedded. Even then, however, the small size of the seeds could hardly cause sufficient irritation of tissues to be of any consequence. Proper technic, however, does not countenance such a procedure. Sound technic requires that, once the

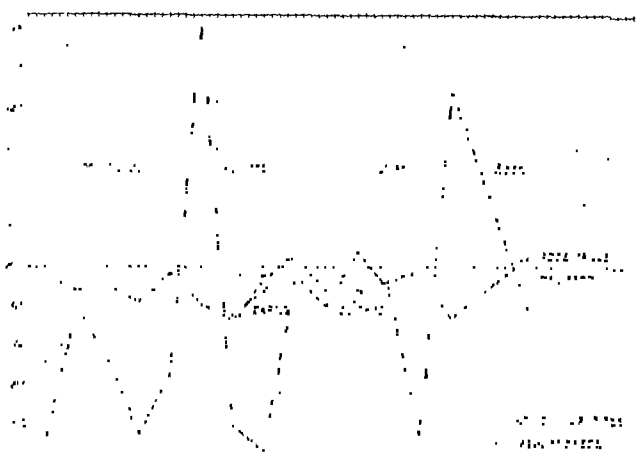

Fig. 4.—Relation of claimed value to measured value.

mandrel comes in contact with the seed, it should not be pushed any farther but should be merely held at this point while the needle is withdrawn with the other hand until it is clear of the opening in the skin, when the mandrel itself is withdrawn. Any irritation produced under these circumstances, therefore, must be produced by the empty needle when first introduced. The only other possible source of tissue irritation comes from the presence within the tissues of the seed acting as a foreign body; this has nothing to do with the smooth or jagged ends of the seed but is solely related to the size of the seed.

In 1934, as far as the American Medical Association is concerned, the control of all matters pertaining to radium and radon was transferred by the Council on Pharmacy and Chemistry to the Council on Physical Therapy. With this control the latter council naturally fell heir to the controversy over the questions of leakage of radon from "seeds" and of tissue irritation arising from any method of preparing the seeds. The Council on Physical Therapy realized at once that, since it was expected by the medical profession to have accurate and reliable information on any subject within the scope of its activities, it was essential that these questions should be thoroughly investigated by those most competent to carry out such investigations. Moreover, the investigators must be specially qualified physicians who had not had any direct or indirect connection with the controversy already mentioned.

The first step was to select a group of consultants who would cooperate with the Council. After thorough consideration by these consultants, by the Radiation Committee of the Council and by the Council as a whole, the following procedure was finally agreed on with reference to the question of leakage:

The different firms who sell or rent radium or radon to the medical profession were to be asked to select an impartial laboratory and submit to it for investigation and report 100 millicuries of radon to be divided as follows:

Twenty-five per cent, thirty seeds each containing 1 millicurie.
Fifteen per cent, ten seeds each containing 1.5 millicuries.
Fifty per cent, twenty-five seeds each containing 2.0 millicuries.
Ten per cent, three seeds each containing 3.0 millicuries.

The seeds were to be furnished in lots of 10 millicuries at intervals of two weeks. The expenses of this investigation were to be met entirely by the firms. The results of the tests were to be submitted by the laboratory chosen to make the investigation directly to the Council on Physical Therapy, which in turn was to refer the report or reports to the special committee of the Council for review; a copy of the report of results was to be sent to each of the firms whose seeds were being investigated. The report of the laboratory was to include a full description of the testing methods which had been employed. Only one firm submitted this evidence.

Besides the foregoing and in order that the Council might have independent information, the Council purchased on the open market 100 millicuries of radon in the following proportions from two firms:

Twenty-five per cent, thirty seeds each containing 1 millicurie.
Fifteen per cent, ten seeds each containing 1.5 millicuries.
Fifty per cent, fifty seeds each containing 2.0 millicuries.
Ten per cent, three seeds each containing 3.0 millicuries.

These were to be supplied in lots as designated by the investigators. The radon was to be made available as follows:

The committee appointed reputable physicians who were willing to cooperate in this venture and who telegraphed or telephoned to the firms an order in the regular way. When the radon arrived, the physicians noted on the carton the date and time of arrival and sent the radon immediately to the National Bureau of Standards in Washington, for testing. The dates of the placing of the orders was controlled by the bureau, which notified the cooperating physician that it was ready for radon at a certain time, so that there was no lost motion.

After the tests had been completed, the seeds were referred to the other members for investigation. The Council paid for the seeds.

The National Bureau of Standards determined the contents of the radon seeds, whether the proper number of millicuries was present at the time of arrival, and whether or not the seeds leaked before sterilization and after sterilization. The method of making these determinations was left to the bureau.

The Committee, cooperating with the physician who was to place the order, examined the advertising

matter and special directions, if any were sent with the radon. The physicians on the committee offered their services free of charge to the Council. They were reimbursed for incidental expenses.

The report of the National Bureau of Standards follows:

We have completed tests for leakage and for millicurie content of 130 seeds which were purchased by Dr. ——— for this purpose. The purchases were distributed as follows as regards nominal content in millicuries: sixty seeds of 1 millicurie each, fourteen seeds of 1.5 millicuries each, 50 seeds of 2 millicuries each and six seeds of 3 millicuries each.

The procedure adopted for test was to measure each seed with a gamma ray electroscope at the hour named for its use on the certificate furnished by the manufacturer. The seed was then enclosed in a sealed glass container and allowed to stand over night. The air was withdrawn from this container into an emanation electroscope the following morning and a determination of the radon content made. The seed was then boiled twenty minutes, again enclosed in a sealed glass container and the emanation measurements repeated as before.

The results of these measurements are shown in the accompanying tables and graph (table 4 and figure 4) where the values, uncorrected for absorption, obtained for the content in millicuries are shown opposite the claimed value and also the amount of leakage in those cases where leakage occurred. The twelve seeds which showed appreciable leakage were all of the "pinched off" gold type. Even in these cases the amount of leakage was less than 1 per cent of the millicurie content, so that from a practical point of view this leakage could be considered as of no consequence.

More important than leakage is the apparent inability of the firms to fill these seeds to radon content claimed on their certificate with the accuracy which they claim. This is plus or minus 1 per cent for any individual shipment. A column of the tables shows the actual percentage of the claimed radon content which we found by gamma ray measurements. These values are also shown in the accompanying chart. The horizontal line represents 100 per cent of claimed value and the plotted points show the actual percentage found for each shipment. The horizontal dotted lines show the tolerance limit of plus or minus 1 per cent as claimed by the firms. Although values of one firm come fairly near to the tolerance, they often exceed it by a factor of 4 or 5. The values of the other firm are much more widely scattered, sometimes being off by as much as 30 per cent.

We are not informed regarding the effect of such inaccuracies upon the medical use of these preparations, but it is apparent that either these seeds should be filled more accurately or the claims of the companies regarding accuracy of filling should be modified to conform with their ability to hold the amount of radon within given limits.

We would appreciate your comments on this report and will be very glad to explain any points we have not made clear. It is our impression that this concludes this investigation, for the present at least, so we are making no further requests for seeds until we hear from you.

L. J. BRIGGS, Director.

This report of the National Bureau of Standards is so explicit that little comment is necessary. One point, however, might be emphasized. The tests have shown that the question of leakage per se is less important than the accuracy of the physical measurements of radon content made by the companies before the seeds are shipped to physicians. And this irrespective of the method of preparing the seeds. If, as shown by the measurements of the National Bureau of Standards, the measurements of radon content made by the companies supplying radon to physicians are so inaccurate (sometimes as much as 30 per cent), it is idle to quibble about occasional leakage of less than 1 per cent.

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

NATIONAL AIR UNIT NOT ACCEPTABLE

Manufacturer: National Mercantile Company, 80 West Washington Street, Chicago.

The National Air Unit is designed to remove pollen, dust and other solid particles from the incoming air for relief of diseases resulting from the inhalation of such particles. It is enclosed in a metal rectangular box 16 inches wide by 10 inches high by 7½ inches deep with intake projection, and the whole is fitted under the ordinary window sash. There are four sets of fixed louvers on the front of the unit. A shutter may be fitted into the intake to permit recirculation of the room air. Rubber weather stripping is provided. The motor is of the induction type for 110 volts alternating current, consuming approximately 45 watts per hour. A Universal motor is available for direct current. The shipping weight is approximately 25 pounds.

The unit is equipped with a four bladed fan which draws the air through the inlet and through two filters, which are composed of oil-soaked spun glass of approximately 1 inch thickness fixed in a loose wire frame. The filters are set at an angle to the intake, so that approximately 50 per cent of the air passes through each filter. There is a small pan in front of the fan which may be filled with water for humidification.

It is claimed by the manufacturer in data submitted from an engineering firm that the filter will remove 99.47 per cent of pollen, dirt and dust from the air. In order to substantiate these claims the Council appointed a competent physician to investigate the unit. It was installed in an ordinary bedroom window.

Greased slides were hung in front of the filters and also in front of the fixed louvers. One tenth Gm. of ragweed pollen was spread on a sheet of paper and laid under the intake opening. The unit was then started and run for an hour, slides being removed at different intervals and examined for pollen. Large numbers of pollen grains were observed, one count reaching 143 pollen grains in ⅛ sq. cm. of area counted on the slide exposed in front of the louvers. Slides exposed on the filter pads themselves showed a much higher count.

The unit was then operated for two weeks during each night until it was fairly well covered with dirt and dust. A new set of slides was then exposed in the same manner as before. No pollen grains were observed, indicating that either the pollen was well adhered to dust particles and the oiled fibers of the filters or had entirely passed through them. A new set of slides was then prepared and placed as described and another 0.1 Gm. of pollen was introduced as on the previous occasion. The slides were removed at varying intervals. Those removed in fifteen minutes averaged 103 pollen grains in ⅛ sq. cm. of area counted, the count dropping somewhat at the end of an hour. Apparently the unit is inadequate for the removal of pollen. Large dust particles were observed on all slides exposed, the particles running as high as approximately 50 microns.

The amount of air delivered roughly averaged 150 cubic feet per minute, as measured by the anemometer. The room was exceedingly stuffy and there was an inadequate intake of air to keep the atmosphere comfortable during hot weather. At first the unit was comparatively noiseless but toward the end of the experiment created considerable noise and disturbance in its operation.

Two pieces of advertising matter were submitted with the unit. A pamphlet, "The National Air Unit," makes claims out of proportion to the Council's findings. Objectionable points were observed such as "relieves hay fever and other respiratory diseases." A filter cannot conceivably relieve a respiratory disease. Another misleading statement is "balanced humidity the year around." Although air conditioning equipment might do this, it is not believed that there is a filter unit at the present time that can substantiate this claim.

The second piece of advertising matter, "Plenty of Clean, Fresh Air For Your Health and Comfort," contains many

exaggerated, unwarranted or misleading claims. According to the Council's findings the air volume claim is in excess of the actual amount of air circulated; the efficiency of the filters is nowhere near the value claimed; there is insufficient provision for proper humidification, and the unit becomes noisy after prolonged use.

In view of the foregoing report, the Council on Physical Therapy voted not to accept the National Air Unit for inclusion in its list of accepted devices because the unit is mechanically unsatisfactory and advertising claims made for it are exaggerated, unwarranted or misleading.

Council on Pharmacy and Chemistry

SPECIAL REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING SUMMARY OF REPORTS SENT TO THE JOURNAL BY PHYSICIANS WHO HAVE USED THE DRUG. IT IS NOT TO BE CONSIDERED AS THE STUDIED OPINION OF THE COUNCIL BUT AS A CONSENSUS OF THE INVESTIGATORS' REPORTS.

PAUL NICHOLAS LEECH, Secretary.

SULFAPYRIDINE

During the past year the drug sulfapyridine (2[para-aminobenzene-sulfonamido] pyridine) has been used experimentally and clinically in this country in the treatment of various types of pneumonia. After careful study, the United States Food and Drug Administration granted the right to manufacturers to distribute the drug in interstate commerce under the stipulations of the act dealing with new drugs. In connection with this study the advice of the Council was sought and received by the Food and Drug Administration. During the period when the drug was under consideration, THE JOURNAL and the Council made every effort to obtain essential information concerning its usefulness and, in so doing, has consulted approximately 100 physicians who have replied to inquiry giving the details of their experiences with the drug. The following statements form a summary of opinion based on the replies which these physicians submitted. In the absence of clinical reports giving detailed information on the drug in the treatment of pneumonia, and because of its importance in present day therapy in pneumonia, the Council submits this summary for the consideration of the medical profession, in addition to the Preliminary Report of the Council which was published in the February 11 issue of THE JOURNAL.

Physicians who were consulted employed this drug in the treatment of approximately 1,800 cases of pneumonia in adults and 650 in children. In some of the cases the drug was employed concurrently with serum; some employed it before and others after the administration of serum, and in many cases the drug was employed alone, without the use of serum.

The replies received lead the Council to believe that it is exceedingly important to discuss typing of pneumonia in connection with the use of this drug before giving further consideration to its use in a given case. It is essential wherever possible to type each case of pneumonia before this drug is administered, because it has been reported by a number of investigators that there are cases of pneumonia which do not respond to this drug and have subsequently responded to the specific antiserums. This cannot be too strongly urged, for at present the reports deal only with the treatment of one year's series of pneumonia cases. The relative virulence of pneumonia during this particular period cannot be established beyond any question of doubt and therefore it is essential to employ this chemical agent over a period of years before the extent of its usefulness both alone and as compared with specific antiserum can be definitely determined. For these two reasons, typing should be continued wherever possible.

One principal finding of those who have employed this drug during the past year is that it is particularly efficacious in the pneumonia of children. It will be recalled, however, that many clinics are not in the habit of employing specific antiserums in the treatment of most of their cases of pneumonia in children. The reason for this is the relatively low mortality of pneumonia in this age group. Therefore the effect of sulfapyridine on the mortality of pneumonia in this age group is of less significance than the fact that the severity of the illness is lessened and its course shortened by the use of sulfapyridine. Because of these facts it seems unjustifiable to compare the usefulness of sulfapyridine with specific antiserum in the treatment of pneumonia in this age group on the basis of mortality rate; at the same time it is acknowledged that it appears to be a useful therapeutic measure in the treatment of children suffering from pneumonia.

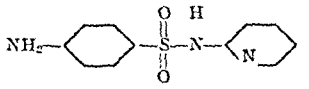
Its use in adults presents a different problem. Some clinics have found that many cases of pneumonia are particularly susceptible to the combined use of specific antiserum and sulfapyridine. Certain investigators enthusiastically prefer sulfapyridine to antiserum in the treatment of pneumonia in adults. Others advocate it more particularly in pneumonias for which there is no available antiserum. Still others find that the comparative effectiveness of sulfapyridine (both alone and combined with specific antiserum) differs in the various types (I, II, III and so on) of pneumococcic pneumonias. There is not, however, at present sufficient evidence on which to base recommendations for the preference of either in the thirty-two types or even in the most common of the types of pneumonia.

Of primary consideration in the clinical evaluation of any new drug is the toxicity which is encountered in its clinical use. A most common and consistent toxic manifestation of sulfapyridine is nausea and vomiting. Strangely enough this is less frequent in children, but occasionally in adults it reaches the point that necessitates discontinuance of the drug. Occasionally toxic manifestations have been encountered suggesting what might be expected, that the toxicity of sulfapyridine is similar to that of sulfanilamide. To the extent that this drug has been used in pneumonia, the incidence of such complications seems to be as low as, if not lower than, with sulfanilamide. Occasional cases of granulocytopenia, hemolytic anemia and various sensitizations with cutaneous manifestations have been encountered. There also seem to be occasional cases of azotemia and very rarely cases in which there is temporary hematuria, which in some cases has been quite severe. Cyanosis has also been encountered and there has been some leukopenia but its relationship to the lessening of the infection has not been clearly demonstrated.

The manner in which this drug acts has not been definitely established. The drug, for the most part, does not produce all of the changes seen at the crisis in pneumonia, whether a normal crisis or one induced by specific antiserum, but produces results more similar to a short course of bronchopneumonia. The temperature falls in several days, as a rule, following administration of sulfapyridine but there is a considerable tendency for lethargy to remain. In fact, there have been occasional cases in which the lethargy has seemed to increase somewhat to the point of mild mental disturbances which are of short duration.

All of these observations lead to the suggestion that, while there is much to be learned about the exact place of sulfapyridine in the treatment of pneumonia, it appears to be a very useful measure in many cases when properly employed. The facts also suggest considerable caution in its use until such time as more evidence is available of its usefulness and safety. Details of and cautions for administering this drug are discussed further in the description (see page 1831 of this issue of THE JOURNAL).

In summary, it may be stated that at present there is every indication that this drug is a useful remedy, and that it remains to be determined just how effective it is and just how well it will compare with antiserum in various epidemics or over a course of years in various types of pneumococcic infections.



An informal report was presented to the Council at its annual meeting in March of this year and the Council voted at that time to accept sulfapyridine for inclusion in New and Nonofficial Remedies and to proceed with the consideration of the submitted brands of the drug.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, *Secretary.*

SULFAPYRIDINE. — 2-sulfanilamidopyridine. — 2-para-amino-benzene-sulfonamido-pyridine $NH_2C_6H_4SO_2NHC_5H_4N$.— N^2-sulfanilyl-2-aminopyridine.—N^1(2-pyridyl) sulfanilamide.

Actions and Uses.—It has been reported that sulfapyridine is an effective chemotherapeutic agent in the treatment of experimental pneumococcic, streptococcic, meningococcic, staphylococcic, Friedländer's bacillary and Welch bacillary infections in mice. Clinically, therapeutic successes have been reported in pneumococcic lobar and bronchial pneumonia, gonococcic, staphylococcic and meningococcic infections. However, the evidence of its effectiveness is convincing only in respect to its use in pneumococcic infections, in which it is apparently about equally effective against all the known types of the pneumococci. Its use in other types of infection must be considered experimental at the present time. In comparison with sulfanilamide, sulfapyridine is irregularly and often poorly absorbed when the drug is given by mouth. The differences in absorption seem to be due to an individual response on the part of the patient. This factor makes rational therapy with the drug more difficult than is the case with sulfanilamide. It also makes it more desirable than ever that the concentrations of sulfapyridine be determined in the blood of patients who are receiving this drug. The drug is, as a rule, conjugated to the acetylated form in the blood and tissues to a higher degree than is sulfanilamide. As the conjugated fraction is inactive from the therapeutic point of view, this again makes therapy at times difficult. As far as is known, the fraction of the drug which is absorbed is excreted mainly by the kidneys in the free and conjugated forms. Excretion is slower than is that of sulfanilamide, and it may be four or five days after the drug has been stopped before it is entirely eliminated from the body.

No patient should be treated with sulfapyridine unless arrangements have been made for daily attention by a physician. This is because of the possibility of serious toxic effects, which, while not frequent, are somewhat unpredictable in their occurrence and presumably have as their basis a peculiar idiosyncrasy. Nausea and vomiting, sometimes very severe, are much more frequent in the course of sulfapyridine therapy than in that of sulfanilamide. Cyanosis, on the other hand, is less marked, as a rule. Acidosis has not been noted, and for this reason it is unnecessary to prescribe sodium bicarbonate when sulfapyridine is being administered. Instances of gross hematuria with and without signs of renal failure have been noted in patients receiving the drug. The mechanism of the production of the hematuria is unknown at the present time. If hematuria occurs, the drug should be stopped. The hematuria may be associated with the formation of acetyl sulfapyridine stones in the pelves of the kidneys. Drug fever, dermatitis, acute hemolytic anemia, toxic hepatitis and agranulocytosis have been noted in the course of sulfapyridine therapy. The toxic manifestations are very similar to those produced by sulfanilamide and occur at the same periods in the course of therapy as do those produced by sulfanilamide. If toxic conditions arise, plenty of water should be given to wash out the drug.

Dosage.—Adequate standards of dosage have not as yet been agreed on by investigators who have used this drug in the treatment of pneumococcic infections. However, the evidence points to the fact that it is important to establish adequate blood levels of the drug within the first day of treatment. Hence in adults suffering from lobar pneumonia large initial doses are given, such as 4 Gm. in a single dose followed by 1 Gm. of the drug every four hours by mouth, this to be continued until the temperature has been normal for at least forty-eight hours; then the dose may be cut to 1 Gm. every six hours and continued until the resolution of the pneumonic process is well under way. At this point the dose of the drug should be reduced to 0.5 Gm. four times a day and should be continued until the lungs are clear. It has been noted that, if treatment with the drug is stopped too soon, recurrence of the pneumonic process may occur. Concentrations of 4 mg. per hundred cubic centimeters or more of free sulfapyridine in the blood seem to be necessary for prompt therapeutic responses to the drug.

In children, the initial dose should be from 1 to 2 Gm., depending on the weight of the child, and then from 0.5 to 1 Gm. every four or six hours until the temperature has been normal for forty-eight hours. Following this, the dose of the drug may be gradually reduced until the lungs are clear.

Adequate standards of dosage have not been worked out for the drug in other types of infections.

For determination of sulfapyridine in body fluids a method developed by E. K. Marshall Jr. and A. C. Bratton (to be published in the near future) is to be recommended.

Sulfapyridine occurs as a white, odorless, practically tasteless, crystalline substance. The melting point is 192 ± 1 degree C. (micro melting point apparatus, rate of heating 4 degrees per minute). It is soluble to the extent of approximately 1 per cent in boiling water and about 0.03 per cent at 20 C.; soluble to the extent of about 0.25 per cent in 95 per cent alcohol; soluble in acetone. It forms water-soluble salts with strong bases or mineral acids.

Place approximately 0.01 Gm. of sulfapyridine in a small test tube and heat cautiously over an open flame until the material melts; a brown color develops and an odor of sulfur dioxide is evolved if heating is prolonged (*distinction from sulfanilamide, which yields a blue-violet color and the odor of ammonia*).

Digest about 1.5 Gm. of sulfapyridine with 75 cc. of boiling water, cool and filter: the saturated aqueous solution of sulfapyridine is neutral to litmus. To 25 cc. of the filtrate add 5 drops of nitric acid and 1 cc. of silver nitrate test solution: the turbidity produced corresponds to not more than 0.01 mg. of chloride. Evaporate another 25 cc. to approximately 10 cc.; add 1 cc. of normal hydrochloric acid and 1 cc. of barium chloride test solution: any turbidity produced corresponds to not more than 0.1 mg. of sulfate ion. Incinerate 1 Gm., accurately weighed, of sulfapyridine: the residue is not more than 0.05 per cent. Add to the residue remaining in the test for ash 0.1 cc. of hydrochloric acid and 0.05 cc. of nitric acid and evaporate on the steam bath. Take up the residue with 0.5 cc. of normal hydrochloric acid and 20 cc. of water; add 10 cc. of hydrogen sulfide water: any darkening produced is not greater than that produced in a control made with 0.01 mg. of lead. Approximately 0.1 Gm. of sulfapyridine shall pass the test for arsenic (U. S. P. XI, p. 436). Dry about 0.1 Gm. of sulfapyridine, accurately weighed, to constant weight at 80 C. under vacuum not exceeding 15 mm. of mercury for approximately five hours: the loss does not exceed 0.5 per cent.

Dissolve approximately 0.2 Gm., accurately weighed, of sulfapyridine, previously dried, in 2 cc. of concentrated hydrochloric acid and 20 cc. of water. Cool and add 15 Gm. of ice. Agitate the solution and titrate with 0.1 molar sodium nitrite solution. Streak the solution on freshly prepared starch iodide paper until an immediate blue streak is obtained. Each cubic centimeter of 0.1 molar sodium nitrite solution corresponds to 0.02493 Gm. of sulfapyridine. The assay is not less than 99.0 per cent nor more than 100.5 per cent. Tablets are assayed by titrating with 0.1 molar sodium nitrite.

SODIUM MORRHUATE (See New and Nonofficial Remedies, 1938, p. 448).

Ampoule Solution Sodium Morrhuate 5% with Benzyl Alcohol 2%, 2 cc.: Each cubic centimeter contains sodium morrhuate 0.05 Gm. (¾ grain) and benzyl alcohol 0.02 Gm. (⅓ grain) in aqueous solution.

Prepared by The Upjohn Company, Kalamazoo, Michigan. No U. S. patent or trademark.

Solution Sodium Morrhuate 5% with Benzyl Alcohol 2%, 30 cc. Vials: Each cubic centimeter contains sodium morrhuate 0.05 Gm. (¾ grain) and benzyl alcohol 0.02 Gm. (⅓ grain) in aqueous solution.

Prepared by The Upjohn Company, Kalamazoo, Michigan. No U. S. patent or trademark.

Ampoule Solution Sodium Morrhuate 10% with Benzyl Alcohol 2%, 2 cc.: Each cubic centimeter contains sodium morrhuate 0.1 Gm. (1½ grains) and benzyl alcohol 0.02 Gm. (⅓ grain) in aqueous solution.

Prepared by The Upjohn Company, Kalamazoo, Michigan. No U. S. patent or trademark.

Solution Sodium Morrhuate 10% with Benzyl Alcohol 2%, 30 cc. Vials: Each cubic centimeter contains sodium morrhuate 0.1 Gm. (1½ grains) and benzyl alcohol 0.02 Gm. (⅓ grain) in aqueous solution.

Prepared by The Upjohn Company, Kalamazoo, Michigan. No U. S. patent or trademark.

RABIES VACCINE (See New and Nonofficial Remedies, 1938, p. 402).

National Drug Company, Philadelphia.

Rabies Vaccine-Human (Phenol-Killed).—Antirabic vaccine prepared according to the general method of Sir David Semple. The brain and spinal cord of rabbits killed on the sixth or seventh day after inoculation with fixed rabies virus are ground in a ball mill for forty-eight hours with physiological solution of sodium chloride containing 1 per cent phenol. The emulsion is incubated at 37.5 C. for twenty-four hours and finally sufficient physiologic solution is added to bring the phenol content to 0.5 per cent. It is kept in the refrigerator for thirty days. Sterility tests are made in fermentation tubes, toxicity tests are made on guinea pigs and safety tests are made on rabbits by intracerebral injections of 0.2 cc. each, the animals being kept under observation for four weeks. Marketed in packages of seven 0.5 cc. ampule-vials (without syringe) and in fourteen 0.5 cc. ampule-vials (with syringe). All doses are of the same potency; one dose is to be given daily over a period of fourteen days.

HUMAN RHEUMATIC VIRUS

The cultivation of a barely visible filtrable pleuropneumonia-like virus [1] from human rheumatic exudates and proof of its pathogenicity for laboratory animals has been reported recently by Swift and Brown [2] of the Rockefeller Institute. The chorio-allantoic membranes of chicken embryos were inoculated with joint exudates. Characteristic pearl-like lesions developed on the egg membranes, "globular structures surrounded with flattened epithelium but containing in their center condensed eosinophil material." As many as twenty-four serial passages of the nodule-producing virus were made. During this process an occasional egg became contaminated with ordinary bacteria. Contaminated egg membranes emulsified in 10 per cent human serum were readily freed from all ordinary bacteria by Berkefeld filtration. The resulting filtrates showed little or no reduction in nodule-producing virus titer.

By the Sabin method of "blind passages" [3] in beef-serum-dextrose-broth the investigators eventually succeeded in growing a minute, barely visible, pleomorphic micro-organism from such filtrates and directly from bacteriologically sterile human rheumatic exudates. Typical chorio-allantoic lesions were produced with these presumably pure virus cultures.

Mice inoculated intranasally with virus cultures developed pneumonia. The inciting agent has thus been transmitted serially in mice by using as the second inoculum ground pneumonic mouse lungs suspended in broth. Ordinary bacteria have been absent from these lungs as determined by both microscopic and culture technics. Further it was found that 0.1 cc. of a pure virus culture will cause iritis and diarrhea [sic] if injected into the vitreous humor of rabbit eyes. Mice inoculated intracerebrally, intravenously or intraperitoneally, however, failed to develop characteristic lesions, even though some of them were obviously sick. The human rheumatic virus, therefore, differs from the mouse arthritis virus recently described by Sabin,[4] which is infectious if injected either intravenously or intraperitoneally in mice.

Thus far no study of serologic specificity has been reported with the human rheumatic agent. Whether or not the Swift-Brown virus is to be considered as a filtrable phase of the streptococcus, therefore, is still an open question. Cultivation of this virus-like micro-organism from joint fluids, pleural exudates and erythema nodosum nodules, however, suggests a new epidemiologic theory of rheumatic disease.

1. Whether the minute filtrable agent causing bovine pleuropneumonia should be classified as a virus or as a midget bacterium is still a controversial question.

ARTIFICIAL INSEMINATION AND ILLEGITIMACY

Whether a child begotten from artificial insemination is legitimate or illegitimate according to the law is an important question. If the child is illegitimate and if the husband of its mother fails to adopt it legally, the child does not acquire inheritable rights from the husband. A child is legitimate if its parents are intermarried when it is begotten or born. Statutes generally legitimatize also the issue of illicit intercourse if the parents intermarry, even though the intermarriage occurs after birth. The fact that conception is effected not by adultery or fornication but by a method not involving sexual intercourse does not in principle seem to alter the concept of legitimacy. This concept seems to demand that the child be the actual offspring of the husband of the mother of the child.

The presumption of law that a child born during wedlock is legitimate is not absolute and conclusive under all circumstances. Even at early common law the presumption was overcome by proof of the husband's sterility.[1] Today the presumption as to legitimacy is more easily controverted than it was in earlier times. Now it is generally recognized by the courts that a child is illegitimate, though born or begotten during marriage, when it is impossible that its mother's husband could have been its father. Every species of legal evidence tending to this conclusion is admissible on the trial of the issue as to its legitimacy.[2]

Artificial insemination can be effected from only two sources: from the semen of the husband of the prospective mother and from the semen of some other male. If the semen of the husband is used, the child obviously is as legitimate as if it were the result of normal and usual intercourse between husband and wife. If the semen of some other male is utilized, the resulting child would seem to be illegitimate. The fact that the husband has freely consented to the artificial insemination does not have a bearing on the question of the child's legitimacy. If it did, by similar reasoning

1. See cases cited in Annotations to 36 L. R. A. (N. S.) 255 and 125 A. S. R. 261.
2. See cases cited in Annotation to 31 A. L. R. 1119.

it might be urged that the fact that a husband had consented to the commission of adultery by his wife would legitimatize the issue resulting from the adulterous connection.

Some advise that all question as to the legitimacy of a child produced from the semen of a male other than the husband of the mother be ignored, apparently relying on the secrecy attendant on artificial insemination and on the presumption of law that a child born during wedlock is legitimate. Such reliance, however, disregards the apparent intent of the husband to confer on the child the rights incident to legitimacy. Those rights, if illegitimacy or even doubt as to legitimacy is frankly recognized, can be assured by adoption proceedings, which ordinarily are comparatively simple.

In many instances of artificial insemination, perhaps in a great majority, the facts may never be known to any one other than husband and wife and the physician involved. There is the possibility, however, that interested relatives may learn of the circumstances and may procure the evidence necessary to overcome the presumption of legitimacy and may thus deprive the child of a share of intestate property. It is the just due of the child that false pride or considerations of delicacy be put aside and that it be given, through adoption proceedings, the protection intended by the husband of the mother when he consents to the artificial insemination of his wife.

SULFAPYRIDINE

In THE JOURNAL, February 11, appeared five communications on sulfapyridine. One was a report of the Council on Pharmacy and Chemistry in which the Council recommended that the preparation be not licensed for sale in interstate commerce at that time. Under the new food and drug act we have advanced greatly in the commercial introduction of new products. For the first time a preliminary survey of the potentiality for good and for harm preceded the exploitation of a drug. The medical profession had opportunity of being informed and its representatives consulted about the drug before any preparation was placed on the open market.

After the Council had published its preliminary report, much evidence was assembled. March 2 THE JOURNAL sent inquiries to all investigators who had clinical experience with the product during the period between its availability for experimental use and its introduction on the market. Replies were received from about 100 investigators; the summation of their replies appears elsewhere in this issue, in a report of the Council on Pharmacy and Chemistry. The results of these investigations yield two significant observations: first, sulfapyridine is a drug of exceedingly great value in certain cases of pneumonia; second, like sulfanilamide it is a drug that needs careful supervision. Its use may probably give rise to as many side reactions as sulfanilamide, if not more—for instance, hematuria. (See article and editorial comment on kidney complications in this issue.)

Sulfapyridine was licensed for sale in interstate commerce on or about March 10. The Council and THE JOURNAL approve the action taken by the government in releasing the drug at that time. The final survey by the Food and Drug Administration was carefully conducted and warranted the release. At present THE JOURNAL is overwhelmed with papers that have been sent in by various investigators. THE JOURNAL is grateful for these contributions. Since, however, most of the original articles are merely confirmatory of work already published, it has been necessary for THE JOURNAL to accept only a few articles. Manuscripts dealing with unusual side reactions or unusual toxic effects or papers reporting extended studies will of course be given special consideration.

Several physicians and organizations have sent inquiries to the headquarters of the American Medical Association asking for an explanation of the relatively high cost of sulfapyridine—approximately 10 cents for a 5 grain tablet in lots of 1,000. A number of factors probably enter into the situation. The drug is patented and therefore not available to free competition. May & Baker, the English concern, assigned its patent rights to Merck & Company of New York. The Calco Chemical Company, it is also understood, claims that it is entitled to a patent and has filed interference claims. One of the ingredients for making the drug, pyridine, has skyrocketed in price from about 35 cents a gallon to approximately $1.75 a gallon. Of course the introduction of any new drug entails tremendous expense, because of the high cost of investigation; in addition, much of the drug must be given free to investigators. For this outlay the firms must be repaid. That the drug might be available and not withheld because of legal complications due to the patent situation, the Calco Chemical Company—a member of the American Cyanamid Corporation—and Merck & Company apparently entered into an agreement whereby the Lederle Laboratories of New York—also a member of the American Cyanamid Corporation—would be the outlet for the pharmaceutic and medical distribution of the drug. The Lederle Laboratories, it will be recalled, have contributed greatly to the development of serums for the treatment of pneumonia, thus being concerned simultaneously with biologic and chemotherapeutic agents. Even with the high price of sulfapyridine, the cost of treatment is considerably less than with the use of antipneumococcus serum. No doubt the commercial investments will soon be equalized, and there is reason to hope that the price of sulfapyridine may be materially reduced in the near future.

Current Comment

BOARD OF TRUSTEES MEETS WITH REGENTS OF COLLEGE OF PHYSICIANS

On April 29, pursuant to its established policy, the Board of Trustees and officers of the American Medical Association conferred with the regents of the American College of Physicians concerning problems of mutual interest, particularly graduate education and the preparation of young men for the practice of internal medicine. Similar conferences will be held with other groups to secure mutual understanding and more effective cooperation from various medical organizations in the specialties where there is joint interest and concern, the purpose being to avoid duplication of effort and unnecessary expenditure of funds, and also to develop efficient leadership, unification of action and satisfactory progress. The discussions on graduate education in the field of internal medicine were led, for the regents of the American College of Physicians, by Drs. O. H. Perry Pepper and Hugh Morgan, and, for the American Medical Association, by Drs. Arthur W. Booth, Austin A. Hayden, Charles Benjamin Wright and R. L. Sensenich of the Board of Trustees and Drs. W. D. Cutter and J. H. Musser of the Council on Medical Education and Hospitals. Most of the other members of the conference also participated in the general discussion. It is proposed to hold similar sessions from time to time with the executive bodies of other leading organizations in the field of the medical specialties.

EFFECT OF SULFAPYRIDINE ON THE URINARY TRACT

A new complication associated with the administration of sulfapyridine is described elsewhere in this issue.[1] Three cases of hematuria, abdominal pain and nitrogen retention were associated with the administration of this drug. All three showed hematuria apparently due to the drug, while in two there was severe abdominal pain of renal and ureteral origin. In the two in which the determination was done there was nitrogen retention due to renal insufficiency. None of the patients had shown evidence of urinary tract disease prior to the administration of the drug for pneumonia. In all instances the manifestations cleared promptly when sulfapyridine was stopped and adequate fluids were administered. Confirmatory evidence of an experimental nature is offered by the recently reported study of Antopol and Robinson,[2] who observed the formation of uroliths in the urinary tract of rats, rabbits and monkeys fed with sulfapyridine. While concretions have been observed after the administration of a single large dose, the results were more striking after a repeated feeding on successive days, although urolith formation varied greatly in the different species and to some extent even in the same species. A few hours after the oral administration of a large dose of sulfapyridine the urinary tract in susceptible animals contained needle-like crystals of the acetyl derivative of sulfapyridine. The crystals in animals that were killed were observed most frequently at the level of the bony pelvic brim. The microscopic appearance of the kidney varied with the degree of urinary stasis. There is, it is pointed out, a suggestion that the crystalline compound, when not excessive, can either be redissolved or washed out. The uroliths consisting of this acetyl derivative permit penetration of x-rays, but it has been observed that calcium can be deposited about these concrements, in which case the shell may become radiopaque. The serious potentialities of this complication of sulfapyridine therapy necessitate careful observation in each case.

THE SURGEON GENERAL'S REPORT

The annual report for the fiscal year 1938 by Surgeon General Thomas Parran of the Public Health Service[1] summarizes health conditions in 1937. The general health conditions in the United States were favorable for 1937, as indicated by preliminary mortality rates. There is an indicated decrease in the death rate of about 3 per cent in 1937 as compared with 1936, and a decrease of more than 8 per cent in the infant mortality rate. The decline in maternal mortality was continued in 1937 as evidenced by a provisional rate of 4.6 per thousand live births, as compared with 5.3 for 1936. In one respect in particular, however, the United States health record was unenviable. For 1937 forty-eight states reported a total of 11,673 cases of smallpox as compared with 7,834 for 1936 and 7,957 for 1935. The number of cases for 1937 was the highest since 1931, although fortunately the case fatality rate was favorably affected by the generally mild, nonvirulent type of smallpox which obtained. The activities of the Public Health Service remain impressive. Active assistance has been rendered to numerous states and territories. Progress in investigative matters was signalized by the organization of the National Cancer Institute and by the laying of the corner stone of the first building to be erected in the new group of structures for the National Institute of Health near Bethesda, Md. Continued attention has been given to evolving a satisfactory control of biologic products, a work in which the actions of the health service have been invaluable. Investigations have been carried on in industrial hygiene, especially with the object of developing means for the protection and improvement of the health of the workers in various fields of industry, and an extensive study of rheumatic heart disease has also been conducted with noteworthy preliminary statistical, clinical and laboratory investigations already reported. Other important activities of the Public Health Service have been related to poliomyelitis, sanitation, grants-in-aid for cancer research, quarantine and immigration activities, mental hygiene and, of course, venereal disease control. The continued improving picture of the country's health is evidence that health conditions are not as black as they are sometimes painted.

ORGANIZATION SECTION

DISTRIBUTION OF PHYSICIANS IN NEW YORK STATE

A decennial study from 1878 of the distribution of physicians in New York State made by Dr. Joseph S. Lawrence and published in the *New York State Journal of Medicine* (39: 199 [Feb. 1] 1939) shows that:

In the entire state the population has increased 167 per cent in the last sixty years, while the number of physicians has increased 477 per cent. In upstate areas the increases have been 86 per cent and 256 per cent respectively. The ratio of physician to population in the entire state is 1: 576, while in upstate alone it is 1: 720. In Greater New York the ratio is 1: 497 and in Manhattan and Brooklyn, where there is the greater concentration of specialists, the ratio is 1: 387. The increase in the population of these two boroughs in the last sixty years is 146 per cent, while the physicians increased 581 per cent. While the physicians increased much more rapidly than the population, the increase in some rural counties was much greater; for example, in Orange County, where the population increased but 50 per cent, the physicians increased more than five times that much, 288 per cent; in Rockland the population increased 124 per cent and physicians 693 per cent; in Warren the population increased 40 per cent and physicians 319 per cent.

Dr. Lawrence finds that the common complaint concerning the age and scientific qualifications of the rural physicians is not justified in New York State. According to the report:

Laboratory and hospital facilities are readily available to the rural resident physician, and journals and county medical society postgraduate courses help him keep abreast of the time as well as the urban resident physician.

The conditions and opportunities of the rural and urban physicians being so nearly equal, one might expect the periods of practice to bear a close resemblance, and they do. Approximately 25 per cent of the physicians in both areas have been in practice less than ten years and another 20 to 25 per cent have been in practice less than twenty years. The assumption that the recent graduate shuns rural practice is only partly correct. Many seek rural locations but, not being successful, are eventually obliged to locate in the cities. But there is another factor operating. Not a few physicians, seeing their most prosperous families forsake the farms for the cities, have followed them advantageously.

The state is well supplied with hospitals, maternity homes and laboratories, the latter being largely under the Division of Laboratories of the State Department of Health.

The report reaches the following conclusions:

Resident physicians and hospitals are distributed throughout the state in such fashion that no area is without medical service. Schuyler County has the lowest ratio of physician to population, 1: 1,298, and the highest is in Dutchess County, 1: 478. In the relation of general hospital beds to the population, the lowest is found in Livingston County, 1: 1,644, and the highest ratio exists in Ontario County, 1: 84. In evaluating these figures, it must be borne in mind that no county is an isolated unit, so that the services of physicians and hospitals of neighboring counties are always available.

Improved conditions for transportation and communications in the rural districts have increased the usefulness of the physician many times over what it was just ten years ago.

The same conditions have led the rural resident to seek the services of the city physician except for emergencies. In some instances this trend has induced rural physicians to move to the cities, at the same time retaining their rural practices.

None the less improved living conditions are attracting young men to locate in the rural areas.

There is no marked difference in the ages of the men practicing in the rural districts as compared with those in the urban districts.

Decreases in population must be marked and prolonged before there is any effect on the number of physicians. Areas of growing population have larger proportions of young physicians.

Nursing service as a part of a public health program demands prompt study.

STATE AND CONTRACT MEDICINE

The annual session of the International Medical Association, held at Copenhagen Aug. 25-28, 1938, heard the report of an inquiry with regard to the effect on the medical profession of a physician's holding several offices or receiving fees from several sources in the practice of medicine. The report was published in the *Revue internationale de médecine professionnelle et sociale* **11**:59 (Nov.) 1938.

Dr. Zahor of Czechoslovakia discussed the general effect of an increase in salaried physicians employed especially by the state or in sickness insurance organizations. He insisted that the most important factor in the problem was the moral effect on the physician. In discussing this, he said: "The limit of medical activities must be the possibility of maintaining honest and conscientious service. This is all the more important since the services of a physician deal with the things most dear to humanity: the health, whether of the individual as with the great majority of practicing physicians or of collective society as is the case with health officials, employees of sickness insurance institutions and so on. . . . It seems unnecessary to say again that the relations between the physician and his patients should be confidential. But actually this is no longer the case, when treatment takes on a certain 'routine.' We would offer all possible resistance to this tendency. The patient is not an object on an assembly line. Sickness is not a number on the register, even though financial considerations may make it necessary to give it such a number. Every patient must be seen as an individual: a good physician should individualize his treatment and always feel the full responsibility which the confidence of the patient places on him.

"The physician holds within his hands health or sickness, capacity to work or invalidity, hope and despair, life and death. It is due wholly to the great value of his services that the physician has acquired his social position, his material and economic level, his moral and political position, and above all his success. Every service that is performed superficially, in haste or with negligence is unworthy of a physician and harmful to his profession. Now, excess of work leads to just these things, and that is why the physician should not be permitted to undertake more labor and more functions than those which he can do honestly and conscientiously. . . .

"From another point of view, the interests of the profession demand that the principles of ethics of the medical group should be observed by every physician. This not only is necessary to preserve the prestige of the profession but also is of importance economically. But necessity knows no law, and poverty destroys the character. For those who cannot

obtain even the minimum necessities to exist, there is great danger that forbidden positions will offer forbidden rebates and will betray the professional group, to its great embarrassment. We must admit that there are already visible within the medical corps certain regrettable symptoms which demand the energetic attention of the professional group if we are to prevent a fall in the moral standard. . . .

"First of all, a professional organization has a duty to prevent situations which injure its members. . . . It should demand that medical employees be obtained exclusively through the medical society. Any institution that has need of the services of a physician should address itself to the medical association to determine the conditions of employment. Each proposal should take into consideration, first, not only the desires and interests of the institutions making the request but also those of the candidates for the position, their economic situation, and their occupations, with a view to avoiding duplications of positions."

OFFICIAL NOTES

RADIO BROADCASTS

The radio broadcasts by the American Medical Association and the National Broadcasting Company, under the title Your Health, continue as previously announced each Wednesday over the Blue network of the National Broadcasting Company at 2 p. m. eastern standard time (1 p. m. central standard time, 12 o'clock mountain time, 11 a. m. Pacific time).

Starting April 30, daylight saving time takes effect in Chicago. The program will therefore be broadcast at the same hour Chicago daylight saving time, which means one hour earlier central standard time, two hours earlier mountain time and three hours earlier Pacific time. In communities where daylight saving time is in effect there will be no change in the hour of the broadcast.

Owing to network conflicts the Chicago broadcast does not occur at 1 o'clock Wednesday but there is a rebroadcast from a recording over station WENR at 8 o'clock each Monday evening, on and after May 1 (8 o'clock Chicago daylight saving time, 7 o'clock central standard time). The program broadcast each Monday is identical with the network program of the preceding Wednesday.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

May 10. The Doctor's Workshop.
May 17. Healthier Babies.
May 24. No broadcast because of radio conflicts occasioned by visit of British sovereigns to the United States.

THE ST. LOUIS SESSION

Special Radio Programs

The following radio programs have been arranged in connection with the annual session of the American Medical Association in St. Louis.

Dr. Irvin Abell, President of the Association, will broadcast over the Blue network of the National Broadcasting Company, Monday, May 15, from 4:15 to 4:30 p. m. central standard time. His subject will be "American Medicine Today" Dr. Rock Sleyster, President-Elect, will broadcast over the Columbia Broadcasting System Monday, May 15, from 3:45 to 4 p. m. Dr. Sleyster will be interviewed by Miss Jane Stafford of Science Service.

Dr. W. W. Bauer, Director of the Bureau of Health Education of the American Medical Association, will broadcast over the Blue network of the National Broadcasting Company, Friday, May 19, from 4:15 to 4:30. He will present a summary of the scientific and sociological developments at the meeting.

ADDRESSES BY OFFICIAL STAFF

DR. W. W. BAUER:

May 9—Logan Howard Preschool Group, Wilmette, Ill.
May 10—Women's Club, Public Meeting, Racine County Medical Society, Racine, Wis.
May 29—South Carolina Public Health Association, Myrtle Beach, S. C.

DR. MORRIS FISHBEIN:

May 8—Arkansas Medical Society, Hot Springs.
May 18—Rotary Club, St. Louis.
May 23—Cornell University Medical School, New York.
May 23—County of Kings and Academy of Medicine, Brooklyn.
May 24—American Surgical Trade Association, Washington, D. C.
May 31—Nurses' Graduation, West Suburban Hospital, Chicago.

MR. JACK LAUX:

May 12—Community Clubs, Joliet, Ill.

DR. PAUL A. TESCHNER:

May 25—Ryburn Memorial Hospital Commencement, Ottawa, Ill.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—S. 840 has passed the Senate, with amendment, proposing that no law of the United States shall be construed to limit the power and authority of the Secretary of War, without reference to line of duty status, to require and incur obligations for hospitalization and medical treatment of persons in active military service, other than those treated in private hospitals or by civilian physicians while on furloughs or leaves of absence in excess of twenty-four hours. The President has signed H. R. 1776, providing for the assignment of medical officers of the United States Public Health Service for duty on vessels of the Coast and Geodetic Survey. H. R. 2320 has passed the Senate providing domiciliary care, medical and hospital treatment and burial benefits to certain veterans of the Spanish-American War, the Philippine Insurrection and the Boxer Rebellion.

Bills Introduced.—S. 2214, introduced by Senator Davis, Pennsylvania, and H. R. 5979, introduced by Representative Van Zandt, Pennsylvania, propose to amend title X of the Social Security Act providing for financial assistance to certain blind persons by adding a provision that the Social Security Board shall not disapprove any plan because it provides for financial assistance to blind persons having an annual cash income of not more than $1,200. S. 2215, introduced by Senator Davis, Pennsylvania, and H. R. 5980, introduced by Representative Van Zandt, Pennsylvania, propose to amend further title X of the Social Security Act by defining the term "needy individuals who are blind" to mean "blind persons in need as defined in a State plan." S. 2226, introduced by Senator Sheppard, Texas, proposes to extend without charge the benefits of the Public Health Service, including benefits other than those received at hospitals or stations of that service, to the wives and dependent children of officers and employees of the Lighthouse Service. S. 2232, introduced by Senator Sheppard, Texas, proposes to provide hospitalization and domiciliary care in Veterans' Administration facilities to retired enlisted men of the Army, Navy, Marine Corps and Coast Guard, who are war veterans, on a parity with other war veterans. S. 2257, introduced by Senator Gurney, South Dakota, proposes to authorize the appropriation

of $1,000,000 for the construction of a veterans' hospital and diagnostic center in the first congressional district of the state of South Dakota. H. R. 2875, introduced by Representative Smith, Washington, proposes that pensions payable to widows and orphans of deceased veterans of the Spanish-American War, Boxer Rebellion or Philippine Insurrection shall be effective as of the date of death of the veteran if claim is filed within one year thereafter. H. R. 5977, introduced by Representative Lesinski, Michigan, proposes to provide pensions to members of the Regular Army, Navy, Marine Corps and Coast Guard varying with the extent of service-incurred disabilities resulting from injury or disease. H. R. 5978, introduced by Representative Sheppard, California, proposes to give to male nurses who served under contract with the War Department between April 21, 1898, and Feb. 2, 1901, the rights, privileges and benefits, including pensions, provided for female Army nurses under contract during the same period. H. R. 6041, introduced by Representative Hendricks, Florida, proposes to authorize an appropriation of $1,750,000 for the construction of a United States Veterans' Administration general medical-surgical hospital and domiciliary facility, with a capacity of at least 500 beds, on or as near to the central east coast of Florida as is feasible.

STATE MEDICAL LEGISLATION

Florida

Bills Introduced.—H. 174 proposes to require the State Board of Health to distribute salvarsan, neosalvarsan, arsphenamine, bismarsen, mapharsen, neoarsphenamine and sulpharsphenamine to the physician of any resident suffering from syphilis or kindred disease requiring the use of any of the drugs stated and financially unable to purchase the necessary drug. H. 419 proposes to require a practitioner of osteopathy to renew his license annually on or before January 1 with the osteopathic board and at that time to pay an annual renewal fee of $5. The bill also proposes to condition the renewal of a license to practice osteopathy on the presentation by the holder thereof of evidence that in the preceding year the licentiate has attended the two day educational program as conducted by the Florida osteopathic association, or its equivalent. H. 577 and S. 272 propose to authorize the State Board of Health to establish a home for the care and treatment of incurable children.

Illinois

Bills Introduced.—S. 332 proposes that corporations not for pecuniary profit organized under the laws of the state shall be liable on their contracts and for their negligence and the negligence of their officers, agents and servants in the course of their authorized duties and their employment. S. 390 proposes to enact a separate physiotherapy practice act and to establish an independent examining committee to examine and license persons to practice physiotherapy. The bill defines physiotherapy as "the method, art or science of treating the human body for hygienic or remedial purposes by the following methods: massage and manipulations with the hands or with any agency or instrument, and the use of such adjuncts as light, heat, air, water, diet, gymnastics and electricity."

Michigan

Bill Introduced.—H. 559 proposes to require all persons licensed to practice medicine, osteopathy or chiropractic to renew their licenses annually with their respective boards of examiners and at that time to pay annual renewal fees of $10. The bill proposes to condition renewal also on the presentation of evidence that the practitioner in the preceding year has attended recognized classes or clinics for the purpose of pursuing postgraduate study of subjects pertinent to his system of healing for not less than ten class hours of fifty minutes each.

Pennsylvania

Bills Introduced.—H. 1358 proposes to enact a law, to be cited as the "Pure Food, Drug and Cosmetic Act," to regulate the manufacture, sale, distribution or advertising of foods, drugs, cosmetics and devices. S. 661 proposes to require every physician attending a pregnant woman during the period of gestation or at delivery to take or cause to be taken a sample of her blood within fifteen days after the time of first examination and to submit the sample to an approved laboratory for a standard serologic test for syphilis. This bill was reported favorably and went to second reading in the senate, April 27. S. 662 was reported favorably to the senate, April 25, proposing to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of a physician's certificate that he or she has submitted to an examination to determine the existence or nonexistence of syphilis and that in the opinion of the examining physician the party is not infected with syphilis or if so infected is not in a stage of that disease which is likely to become communicable.

South Carolina

Bill Introduced.—H. 845 proposes to authorize the organization of corporations to operate nonprofit hospital service plans whereby hospital care may be provided by the corporations through hospitals approved by the South Carolina Hospital Association to persons subscribing to the hospital service plans.

Wisconsin

Bill Introduced.—A. 719, to amend the pharmacy practice act, proposes that the act shall not interfere with the dispensing of drugs, medicines or other articles by physicians *in an emergency, provided only such drugs shall be kept in stock by a physician as are necessary for emergency use.* The present law provides that the act shall not interfere with the dispensing of drugs, medicines or other articles by physicians. This bill, if enacted, would seem to permit a physician to dispense only in an emergency.

WOMAN'S AUXILIARY

California

The auxiliary to the San Diego County Medical Association met at the University Club in San Diego with eighty members in attendance. A three-act comedy by Mrs. Willard Newman entitled "How Do You Like Your Medicine? or Can You Take It?" was presented.

Mrs. Frances Parish described the service given blind persons by the "seeing-eye dog," at a meeting of the auxiliary to the San Francisco County Medical Society January 17.

At the January meeting of the auxiliary to the San Joaquin County Medical Association, Miss Eileen Clark spoke on the "Function and Needs of the Juvenile Court in the Field of Child Guidance."

Mrs. William Renfry Hunt reviewed "Fifty Years a Country Doctor" by William MacCarthey at the January meeting of the auxiliary to the Santa Barbara Medical Society. Members attended a Forum on "Socialized Medicine," held by the American Association of University Women January 18.

At recent meetings of the auxiliary to the Santa Clara Medical Association, Dr. Edward Liston of Palo Alto spoke on "Medical and Hospital Insurance" and Dr. Walter H. Brown, professor of hygiene at Stanford University, on "Public Health, Past and Present."

Indiana

The auxiliary to the Marion County Medical Society held the annual dinner dance with the society January 10 at the Indianapolis Athletic Club with 480 doctors and their wives in attendance.

The auxiliary to the Vigo County Medical Society held a meeting in Terre Haute recently. Mr. Phil Brown gave an illustrated lecture on Williamsburg.

Minnesota

Dr. George A. Earl, president of the Minnesota State Medical Association, addressed the auxiliary to the association at the Women's City Club, St. Paul, February 1 on "The Medical Outlook." Mrs. W. B. Roberts is president.

Dr. J. M. Hayes addressed the auxiliary to the Hennepin County Medical Society February 3 on "Socialized Medicine."

The auxiliary to the Stearns-Benton Counties Medical Society met in St. Cloud February 9. Mrs. R. N. Jones reviewed "The Citadel." The auxiliary has placed *Hygeia* in eleven schools of these counties.

The auxiliary to the Washington County Medical Society met February 14. Mrs. E. Sydney Boleyn led a discussion of government-controlled medicine and Mrs. C. E. Proshek spoke on Czechoslovakia.

Mississippi

Mrs. Sidney Johnston reviewed "The Horse and Buggy Doctor" by Dr. Arthur E. Hertzler recently before the auxiliary to the Issaquena-Sharkey-Warren Counties Medical Society.

The auxiliary to the Fourth District Medical Society was organized by Mrs. John Howell, president of the auxiliary to the Mississippi Medical Association, February 9. Mrs. P. B. Brumby was elected president. Members of this group have already placed several subscriptions to *Hygeia* in the libraries and public schools of the district.

Pennsylvania

The auxiliary to the Allegheny County Medical Society met January 24. Mrs. Joseph P. Dobo spoke on socialized medicine. Judge Gustav L. Schramm of the Juvenile Court of Allegheny County also addressed the meeting.

The auxiliary to the Berks County Medical Society held its third Annual Health Conference in Reading January 21. Dr. Hugh P. Shellabear, president, Berks County Medical Society, awarded the prizes for the essay contest on "Why Is Health Education Necessary?" which was conducted in the county and city high schools. The films "Prevention of Burns to Children," "The Conquest of Diphtheria" and "The Control of Pneumonia" were shown. Mrs. Augustus S. Kech, president of the auxiliary to the American Medical Association, 1937-1938, addressed the meeting. Dr. Harry B. Corrigan spoke on "Communicable Diseases and Their Prevention."

The auxiliary to the Chester County Medical Society met in West Chester January 17. Mrs. Joseph Scattergood Sr. discussed the proposed National Youth Administration project at Darlington Seminary, West Chester, for the care of fifty girls, aged from 17 to 30, from families on relief from the five counties of southeastern Pennsylvania. This project offers an opportunity somewhat similar to that for boys in the CCC camps.

The auxiliary to the Delaware County Medical Society was the guest of the society at its annual meeting January 12. The speaker was Mr. David McCahan, of the University of Pennsylvania, whose subject was "Building and Insuring the Family Financial Program." It was voted to donate ten subscriptions to *Hygeia* to be placed in schools and libraries of Delaware County. Mrs. Arthur Whitney discussed socialized medicine.

INCREASING SICKNESS IN SCOTLAND

The Department of Health for Scotland has recently issued the "Seventh Report on Incapacitating Sickness in the Insured Population of Scotland." This covers the period from July 1, 1936, to June 30, 1937, during which there was an average incapacity per insured due to sickness of 14.92 days per insured person. Part of the increase in the year 1936-1937 is due to an excess of influenza cases, but when this disease is excluded there is an increase from 8.8 days in 1931-1932 to 10.9 days in 1936-1937. Studies of similar bodies of employed workers in the United States over several years and including influenza gives an average of about 9.0 days lost through sickness per worker annually. It cannot be claimed that the absolute number of days is exactly comparable, as the Scottish statistics apparently include a larger percentage of chronic cases than those for the United States. The significant and apparently wholly justifiable basis of comparison would seem to be between the continuously increasing morbidity under insurance and the constant or slowly decreasing days of sickness under private practice.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Society News.—The Los Angeles County Medical Association was addressed April 6 by Drs. Steele F. Stewart Jr. on "Early Diagnosis and Treatment of Congenital Dislocation of the Hip"; Ward M. Rolland, "Supracondylar Fractures of the Elbow," and Harold E. Crowe, "Short Hospitalization of Fractures."——Among others, Dr. John J. Shea, Memphis, Tenn., addressed the Los Angeles Society of Ophthalmology and Otolaryngology April 17 on "Management of Fractures of the Face."——Dr. William D. Sansum, Santa Barbara, discussed "The Problem of the Underweight Patient" before the Hollywood Academy of Medicine April 13.

COLORADO

Personal.—Thomas Russell Garth, Ph.D., since 1930 professor of experimental psychology, University of Denver, died April 20. In 1912 Dr. Garth assisted in the Rockefeller Hookworm Investigation and in 1930-1931 headed the expedition to study color blindness of Indians, and in 1935-1937 the expedition to study the foster Indian child in white homes; he also served with other expeditions to study the psychology of the Indian since 1919.——Dr. William N. Beggs, Denver, was guest of honor at a dinner given by the Colorado medical alumni of Washington University April 8; he graduated in 1886.——Dr. Edward G. Billings, director of the liaison department of psychiatry, Colorado General Hospital, recently received $30,000 from the Rockefeller Foundation for the continuation of his work, according to the Denver *Medical Bulletin*.

GEORGIA

Changes in Health Officers.—Dr. Albert G. LeRoy, Atlanta, has been appointed commissioner of health of Toombs County, effective January 1, and Dr. Robert F. Young, Cartersville, of Bartow County. Dr. Garland L. Weidner has been chosen assistant health officer of Atlanta. Dr. Roland A. Brown, Macon, has been appointed assistant city-county health officer of Bibb County, succeeding Dr. Herbert F. Laramore, who has accepted a position on the staff of the U. S. Veterans' Hospital in Los Angeles, it is reported. Dr. Richard C. Shepard, La Fayette, has resigned as health commissioner of Catoosa and Walker counties, effective April 15, to engage in private practice.

District Meetings.—The Fifth District Medical Society held its spring meeting April 13 at the Academy of Medicine in Atlanta. Dr. Edgar Hill Greene, Atlanta, president, Fulton County Medical Society, gave the address of welcome. Drs. A. Benson Cannon, New York, and Grady N. Coker, Canton, president, state medical association, discussed "Comparative Value of Antisyphilitic Drugs" and "Modern Trends in Medical Practice" respectively. A symposium on the clinical aspects of pellagra was presented by Drs. Tom Douglas Spies, Cincinnati, Virgil P. W. Sydenstricker, Augusta, and James McLester, Birmingham, Ala.——The Tenth District Medical Society was addressed at Athens recently, among others, by Drs. John Weyman Davis, Athens, on "Treatment of Fractures of the Neck of the Femur" and Joseph Righton Robertson, Augusta, "Internal Urethrotomy."——Dr. Leo W. Koster, New York, discussed certain phases of surgery before the Second District Medical Society at Colquitt April 14.

ILLINOIS

Society News.—Dr. Roland M. Klemme, St. Louis, discussed "Neuralgias of the Head and Face: Differential Diagnosis and Treatment" before the Adams County Medical Society, Quincy, April 10. Dr. Franklin E. Walton, St. Louis, discussed "The Surgeon's Approach to Diseases of the Gallbladder" before the society recently.——The Peoria City Medical Society was addressed March 21 by Dr. James H. Hutton, Chicago, on "Diagnosis and Treatment of Neglected Endocrinopathies"; March 7 by Dr. Raymond M. Rice, Indianapolis, "Clinical Use of Female Sex Hormones," and February 21 by Dr. August A. Werner, St. Louis, "Influence of the Endocrines on Growth and Development."——Dr. Charles E. Galloway, Evanston, Ill.,

discussed "Pathology of the Cervix" before the Sangamon County Medical Society, Springfield, April 6.——Drs. Howard A. Rusk and Harold G. Newman, St. Louis, addressed the Marion County Medical Society, Centralia, April 20, on "Diagnosis and Treatment of Undulant Fever."

Chicago

Pneumonia Service.—A twenty-four hour service for the distribution of pneumonia serum and typing of sputum from pneumonia patients has just been established by the Chicago Board of Health. While the twenty-four hour service is available to physicians only at the department's branch laboratory at the Municipal Contagious Disease Hospital, the service will be available at the central laboratory, located in the city hall, room 707, during specified hours. Detailed information may be obtained from the department of health.

INDIANA

New State Program in Psychiatry.—The state department of public welfare recently inaugurated a program to establish part time mental hygiene clinics to serve most of the communities in Indiana. With the approval of the state medical society, five physicians were given membership in the Indiana Council on Mental Hygiene to be a liaison group between the department of public welfare and the profession. In counties where it is proposed to offer services of a mental hygiene clinic team, the program is first submitted to the county medical society and only after an invitation has been extended by the society is a clinic established. Dr. Exie E. Welsch, who has been directing the mental hygiene program of the bureau of maternal and child health of the state board of health, has been transferred to the bureau of mental care of the state department of public welfare. She will assist Dr. George C. Stevens, director, division of medical care, in organizing the clinics. The liaison committee and the committee on mental health of the state association have agreed that there was no need for two distinct mental hygiene programs with similar aims being conducted in the state board and the department of public welfare.

IOWA

Personal.—Dr. Joseph M. Casey, Fort Madison, was guest of honor at a banquet given by the Fort Madison Medical Society recently in recognition of his completion of fifty years in the practice of medicine.——Dr. Henry A. Meyers, Davenport, was presented with a gold wrist watch by the Scott County Medical Society at a meeting January 3 following his resignation as secretary; he had held the position since 1930.

Public Meetings.—Dr. Ludvig Hektoen, Chicago, executive director, National Advisory Cancer Council, addressed a public meeting at the Hoyt Sherman Place, Des Moines, recently. The meeting was sponsored by the Iowa division of the Women's Field Army, Iowa. Dr. Thurman B. Rice, Indianapolis, gave a public lecture March 5 on "Problems of Sex Education."

KANSAS

Society News.—Dr. Axel N. Arneson, St. Louis, discussed "Treatment of Cancer of the Body of the Uterus" before the Shawnee County Medical Society April 10 in Topeka.——Dr. John M. Waugh, Rochester, Minn., addressed the Sedgwick County Medical Society, Wichita, April 4, on "Management of the Acute Abdomen."

Society Observes Fiftieth Anniversary.—The Golden Belt Medical Society observed its fiftieth annual meeting at Junction City April 13; the speakers were Drs. Arthur E. O'Donnell, who reported a case of screw worm in the nose; Thomas G. Orr, Kansas City, Mo., "Treatment of Peritonitis"; Jacob A. Bargen, Rochester, Minn., "Medical and Preoperative Management of Intestinal Obstruction," and John M. Porter, Concordia, "A Kansas Society Fifty Years Old."

Postgraduate Courses.—A series of postgraduate courses is being held throughout the state under the auspices of the state medical society and the state board of health with the assistance of social security funds. A four week course in obstetrics and pediatrics opened March 20, to reach Beloit, Smith Center, Hays, Ellsworth and Abilene. Drs. William F. Mengert and John H. Randall, Iowa City, are giving the instruction in obstetrics, and Drs. Jean V. Cooke, St. Louis, and Julian D. Boyd, Iowa City, the instruction in pediatrics. A similar course was scheduled for Leavenworth, Sabetha, Clay Center, Wamego and Lawrence, and the instructors were Drs. William J. Dieckmann and Morris Edward Davis, Chicago, in obstetrics and Mandel L. Spivek, Chicago, pediatrics. A course opened March 9 on venereal disease; it was to continue through April 21 with Dr. Joseph V. Van Cleve, Wichita, as the speaker. Dr. Nathan A. Womack, St. Louis, conducted the postgraduate course on cancer control, which began March 20.

KENTUCKY

State Board Sponsors Radio Program.—The Kentucky State Board of Health inaugurated a series of fifteen-minute radio broadcasts over station WHAS, Louisville, in March. The programs are broadcast Saturday afternoons at 4:45 central standard time. The first program reviewed the organization of the Kentucky State Medical Association and the state board of health and the series continues with dramatizations of the present activities of both organizations.

Society News.—Dr. Percival Bailey, Chicago, delivered the annual Alpha Omega Alpha Lecture of the Jefferson County Medical Society April 21 on "Indications for Operation in Cases of Tumor of the Brain." Drs. George A. Hendon and Pat R. Imes, Louisville, addressed the society April 17 on "Multiple Abscesses of the Liver" and "Immediate Treatment of Automobile Injuries" respectively.——George F. Cartland, Ph.D., Kalamazoo, Mich., addressed the Louisville Obstetrical and Gynecological Society April 24 on "Pituitary Ovarian Relationship with Reference to Use of Pregnant Mare Serum in Therapy."——Dr. Morris Edward Davis, Chicago, addressed a joint meeting of the Jefferson County Medical Society and the Louisville Obstetrical and Gynecological Society, March 6, on "Present Day Treatment of Hemorrhage Late in Pregnancy."

LOUISIANA

Southern Hospital News.—The new eight story addition to the Baptist Hospital, New Orleans, adding seventy-four beds to the 200 bed institution, has been completed at a cost of about $180,000.

Society News.—Dr. Charles J. Bloom, New Orleans, addressed the Iberville Parish Medical Society at Plaquemine March 3 on "Appendicitis in Infancy and Children."——Dr. Jay W. Cummins, Monroe, addressed the Ouachita Parish Medical Society recently on "The Rationale of Blood Transfusion" and Dr. Robert M. Simonton, "The Toxicology of Sulfanilamide."——Among others, Dr. Eugene M. Robards Jr. addressed a recent meeting of the Bi-Parish Medical Society at Jackson on "Involutional Melancholia and the Depressive Manic State."——It was decided at the recent annual meeting of the Tuberculosis and Public Health Association to hold the sixteenth annual session in Monroe; this will be the first time the meeting has been held out of New Orleans.——The Orleans Parish Medical Society held its joint scientific and first quarterly executive meeting April 10; the speakers were Drs. John H. Musser and Robert A. Wise on "Bacillus Pyocyaneus Meningitis, a Report of Six Cases"; Clyde Brooks, "Toxicity of Sulfanilamide and Related Compounds," and Dean H. Echols, "Tic Douloreux."——Dr. Michael E. DeBakey addressed the East Baton Rouge Parish Medical Society April 12 on "Surgical Amebiasis."

MAINE

Osteopaths Defeated in Maine Legislature.—The Maine legislature has just defeated the legislative document (H. P. 1706) (L. D. 873) which required hospitals receiving public funds to admit osteopathic physicians to practice, to treat and care for their patients and to furnish laboratory service for osteopathic physicians. The committee reported "ought not to pass" 7 to 3. After a long debate, the bill was defeated 72 to 26.

MASSACHUSETTS

Society News.—Dr. Meredith F. Campbell, New York, discussed "Urogenital Diseases of Infants and Children" before the Worcester District Medical Society April 12.

Health Week in Worcester.—The first "Worcester health week" was observed March 4-10 under the auspices of the health education committee of the local Young Men's Christian Association in cooperation with many other organizations. About thirty-eight health talks were scheduled in cooperation with the Worcester District Medical Society and about twenty-four showings of films related to health topics.

MICHIGAN

Society News.—Dr. Samuel M. Feinberg, Chicago, discussed "Mold Allergy" before the Michigan Allergy Society, Ann Arbor, March 16.——Dr. Plinn F. Morse, Detroit, discussed "Causes of Sudden Death" before the Ingham County Medical Society March 21.——Dr. John Warrick Thomas, Cleveland, addressed the Jackson County Medical Society in Jackson April 18 on "Allergy in General Practice."

Changes in State Health Department.—A new branch laboratory of the Michigan Department of Health was recently established in the Pinecrest Sanatorium at Powers. Dr. Filip C. Forsbeck, director of the bureau of epidemiology, resigned to accept a position with the U. S. Public Health Service, effective March 1. Dr. Forsbeck will make a study of dysentery in the Ohio River Valley; his headquarters will be in Cincinnati. Dr. Arthur W. Newitt, Lansing, who has been chief of the division of tuberculosis, has been appointed acting director of the division of epidemiology.

The State of Health.—The general death rate in Michigan in 1938 was 9.9, according to provisional figures published in the state medical journal. There were 50,470 deaths reported as compared with 53,468 in 1937. The birth rate was 18.7; the total number of births was 95,385 as compared with 91,566 in 1937. A new low point was established for infant mortality with a rate of 45.14 deaths per thousand live births. The maternal mortality rate was 3.56 deaths per thousand live births. Deaths caused by automobile accidents dropped to tenth place. This group totaled 1,444 in 1938 as compared to the all time high total of 2,175 in 1937. Deaths from tuberculosis declined from 2,119 in 1937 to 1,865 in 1938.

Neuropsychiatric Institute Dedicated.—The Neuropsychiatric Institute of the University Hospital, Ann Arbor, was opened February 11 with Alexander G. Ruthven, Ph.D., president of the university, presiding. Dr. Rock Sleyster, Wauwatosa, Wis., President-Elect, American Medical Association, gave the dedicatory address. The institute is a five story wing adjoining the hospital on the north with facilities for the care of sixty adult patients and twenty-three children. There are also increased teaching facilities, including an auditorium seating 140 persons on the subbasement floor and classrooms on two other floors. A large portion of the building will be devoted to research, and the neuropathologic laboratory and photographic department, which will also take care of the photography for the main hospital, are both especially well equipped, according to the *University Hospital Bulletin*. By a recent act of the state legislature, the institute will treat only voluntary patients and committed patients will not be admitted. The study and treatment of incipient or threatened mental disease will be emphasized and research will be directed toward the preventive aspects of psychiatry.

NEW MEXICO

State Medical Meeting at Gallup.—The fifty-seventh annual meeting of the New Mexico Medical Society will be held at the El Rancho Hotel, Gallup, May 11-13, under the presidency of Dr. Eugene W. Fiske, Santa Fe. Governor John E. Miles will deliver the address of welcome. Other speakers will include:

Dr. Robert W. Lamson, Los Angeles, Allergy and Pseudo-Allergy in General Practice.
Dr. William Philip Corr, Riverside, Calif., The Management of Diabetes.
Dr. Benjamin H. Orndoff, Chicago, Early Changes in the Endometrium, Diagnosis and Management.
Dr. Henry J. Goubeaud Jr., Brooklyn, Ruptured Uterus.
Dr. Jack G. Hutton, Denver, The Diagnosis of Syphilis.
Dr. Nelson Paul Anderson, Los Angeles, The More Common Skin Diseases.
Dr. Ralph M. Stuck, Denver, Spinal Injuries with Nerve Damage.
Dr. Rollin Russell Best, Omaha, The Physiological Biliary Flush as an Aid in the Management of Biliary Tract Disease.
Dr. George B. Kent, Denver, The Proper Management of Surgical Lesions of the Biliary Tract.
Dr. E. Payne Palmer, Phoenix, Ariz., Suspicious Cancer Symptoms.
Dr. Harold L. Thompson, Los Angeles, The Surgical Treatment of Peptic Ulcer.
Dr. Paul J. Connor, Denver, Objective Signs in the Diagnosis of Endocrinopathies.
Dr. Howard F. West, Los Angeles, Symptomatology and Etiology of Spontaneous Hypoglycemias.
Dr. Oscar B. Nugent, Chicago, Eye Conditions of Interest to the General Physician.
Dr. Francis C. Goodwin, El Paso, Texas, Use of Bone Traction in Scoliosis.
Dr. Jacob Travis Bennett, El Paso, Common Feeding Difficulties in Pediatric Practice.
Dr. William H. Daniel, Los Angeles, Proctology for the General Practitioner.
Dr. Charles H. Arnold, Lincoln, Neb., Splanchnic and Brachial Block Anesthesia.
Dr. Romeo J. Lajoie, Los Angeles, Angina Pectoris.

There will be round table luncheons Thursday and Friday. Entertainment will include a buffet dinner, the annual smoker, dinner dance, reception, luncheon and motor trip.

NEW YORK

New Tumor Clinic.—The Samaritan Hospital, Troy, opened a tumor clinic April 6 with Dr. Victor C. Jacobsen, associate professor of medicine, Albany Medical College, as director. Dr. Jacobsen will be consultant in pathology, Dr. William J. Hoffman, New York, consultant in neoplastic diseases, and Robert A. Patterson, Ph.D., Troy, consultant in biophysics. Sessions will be held every Thursday morning.

New York City

Hospital News.—Dr. Charles Rosenheck delivered the annual memorial address to commemorate the life and work of Dr. Henry W. Frauenthal, founder of the Hospital for Joint Diseases, March 7.——Dr. Howard Fox gave a lecture at Beth Israel Hospital recently on experiences of a dermatologist in the tropics.

Stock Exchange Discontinues Medical Department.—The medical department of the New York Stock Exchange was discontinued as an Exchange activity April 1, newspapers reported recently. Dr. Francis H. Glazebrook, medical director since 1931, has retired and Dr. Robert S. Millen, Westbury, N. Y., will take over the quarters and operate a clinic on his own behalf, it was announced.

Society News.—Speakers at a meeting of the New York Roentgen Society April 17 were Drs. Marcy L. Sussman, Simon Dack and Arthur M. Master on "The Roentgen Diagnosis of Myocardial Infarction" and Dr. William Snow, "X-Ray Visualization of Soft Structures of Pregnancy."——A symposium on eugenics and genetics was recently presented at a meeting of the International and Spanish-Speaking Association of Physicians by Maurice A. Bigelow, Sc.D., and Norman E. Hines, Ph.D., Hamilton, N. Y., and Benjamin C. Gruenberg, Ph.D.——A symposium on the prevention and treatment of automobile accidents was presented before the Medical Society of the County of New York recently; the speakers were John J. Seery, first deputy police commissioner, and Carroll E. Mealey, commissioner, bureau of motor vehicles, New York State, and Drs. David J. Kaliski, Conrad Berens and John J. Moorhead.——The New York Surgical Society devoted its meeting April 12 to a symposium on duodenal ulcer; the speakers were Drs. Richard Lewisohn, James William Hinton, Roland L. Maier and John J. Westermann Jr.

Medical Committees for the Fair.—The committees in charge of arranging medical and health exhibits for the New York World's Fair include the following in addition to those published in THE JOURNAL, April 22, p. 1609:

Dr. Wilson G. Smillie, exhibit on health administration, sponsored by the American Public Health Association.
Dr. Adolph G. G. De Sanctis, child health, growth and development committee, Mead Johnson & Co.
Waite A. Cotton, D.D.S., dentistry and oral hygiene committee, Dental Society of the State of New York.
John Mohler, D.V.M., veterinary safeguards and public health, American Veterinary Medical Association.
Dr. Harvey B. Matthews, maternal health, Maternity Center Association.
Dr. Howard W. Haggard, New Haven, Conn., maze of superstitions, the Bayer Company.
Dr. Milton J. Rosenau, Chapel Hill, N. C., milk control, Cherry-Burrell Corporation.
Dr. Francis M. Rackemann, Boston, allergy, Lederle Laboratories, Inc.
Charles-Edward A. Winslow, Dr.P.H., New Haven, Conn., health in the home, the John B. Pierce Foundation.
Leonard Greenburg, Ph.D., industrial sanitation, West Disinfecting Company.
Dr. Daniel B. Kirby, conservation of sight and education of the blind, New York Institute for Education of the Blind.

Dr. Putnam Appointed Professor of Neurology—Other Changes.—Dr. Tracy J. Putnam, since 1934 professor of neurology, Harvard Medical School, Boston, has been appointed professor of neurology and neurosurgery in Columbia University College of Physicians and Surgeons, effective October 1. He will also serve as director of services of neurology and neurosurgery at the Neurological Institute of the Columbia-Presbyterian Medical Center. Dr. Vernon W. Lippard, director of the Commission for Study of Crippled Children of the City of New York, has been appointed assistant dean of the medical college. According to an announcement, Drs. Charles A. Flood and Lawrence W. Sloan have resigned as assistant

deans to enter private practice. A native of Boston, Dr. Putnam took his medical degree at Harvard in 1915. He was Moseley traveling fellow at the University of Amsterdam, 1924-1925; Arthur Tracy Cabot fellow in charge of laboratory of surgical research at Harvard, 1925-1926; associate in surgery, Peter Bent Brigham Hospital, 1925-1928. Becoming assistant in surgery at Harvard in 1926, he subsequently served in various capacities until 1934, when he was named professor of neurology. He was visiting neurologist to the Boston City Hospital for many years. Dr. Lippard was born in Marlboro, Mass., in 1905 and graduated at Yale University School of Medicine, New Haven, in 1925. He has been associate attending pediatrician at New York Hospital and associate in pediatrics at Cornell University Medical College.

OHIO

Society News.—Dr. Henry L. Bockus, Philadelphia, addressed the Academy of Medicine of Cleveland April 21 on the diagnosis and treatment of jaundice. Dr. Leroy U. Gardner, Saranac Lake, N. Y., discussed silicosis before the academy recently.

Changes in Hospital Superintendents.—Dr. Fred G. Carter, superintendent of Christ Hospital, Cincinnati, has been appointed superintendent of St. Luke's Hospital, Cleveland, to succeed Dr. Charles S. Woods, who has resigned. Dr. Charles T. Way has been named medical director of St. Luke's and Dr. Willard C. Stoner, medical director for many years, is now medical consultant. Dr. Carter went to Cincinnati in 1935 from St. Paul, where he was for ten years superintendent of Ancker Hospital. He has been president of the Minnesota Hospital Association, the American College of Hospital Administrators and the Ohio Hospital Association; he is now president-elect of the American Hospital Association. To succeed Dr. Carter at Christ Hospital in Cincinnati, Dr. Merrill F. Steele, superintendent of Grant Hospital, Columbus, has been selected.

OKLAHOMA

Society News.—Drs. Rufus Q. Goodwin and Wilbur Floyd Keller, Oklahoma City, addressed the Pottawatomie County Medical Society, Shawnee, April 15 on "Clinical and Therapeutic Aspects of Anemia" and "The Pathology of Anemia" respectively.——Drs. Alfred R. Sugg and Ennis M. Gullatt, Ada, addressed the Pittsburg County Medical Society recently on "Perinephritic Pathology" and "Empyema" respectively.——Drs. Alvin Ray Wiley and Victor K. Allen, Tulsa, addressed the Muskogee County Medical Society recently on "Relation of Endocrines to Neoplasms of the Breast" and "Individual Technic in Anorectal Surgery" respectively.

PENNSYLVANIA

Dr. Wyant Honored.—Dr. John B. F. Wyant, Kittanning, was honored by the school children of the city March 28 in recognition of his completion of fifty years in the practice of medicine and for his interest in school health. He was presented with a radio and a plaque. A floral tribute was presented to the physician by the Armstrong County Medical Society, for which he has been secretary for nearly forty years. Dr. Wyant also served fifteen years as a member of the board of trustees of the state medical society and acted as chairman of the board for several years.

Philadelphia

Dr. Hamill Receives Strittmatter Award.—Dr. Samuel McClintock Hamill was awarded the Dr. I. P. Strittmatter Gold Medal by the Philadelphia County Medical Society April 12. Dr. Hamill, who has practiced in Philadelphia since 1890, has been active in child welfare work for many years. Among other activities he was chairman of section I on medical service of the Hoover White House Conference on Child Health and Protection and during the past four years was chairman of the Pennsylvania Emergency Child Health Committee. He has served as president of the American Academy of Pediatrics, the American Pediatric Society and the Philadelphia Pediatric Society, as chairman of the Section on Diseases of Children of the American Medical Association and was the first chairman of the section on pediatrics of the Medical Society of the State of Pennsylvania. In addition he was president of the American Association for the Study and Prevention of Infant Mortality in 1915 and again under its later name, the American Child Health Association, from 1931 to 1935. From 1901 to 1919 he was professor of diseases of children at the old Philadelphia Polyclinic and College for Graduates in Medicine and for another year at the University of Pennsylvania Postgraduate Department of Medicine.

Pittsburgh

Society News.—Dr. Allen O. Whipple, New York, delivered the Stewart Memorial Lecture of the Pittsburgh Academy of Medicine March 28 on "Diagnosis and Treatment of Pancreatic Lesions."——Dr. Albert D. Kaiser, Rochester, N. Y., addressed the Pittsburgh Pediatric Society April 14 on "Certain Phases of the Tonsil Problem in Children."——Speakers at a meeting of the Allegheny County Medical Society April 18 were Drs. Harry M. Margolis, on "Protrusions of Lumbar Intervertebral Disks as a Cause of Low Back and Sciatic Pain"; Louis H. Landay, "Coronary Heart Disease"; Joseph H. Barach and Lazarus Lewis Pennock, "Diagnostic Value of Occult Hematuria: Based on a Study of 3,000 Urinary Sediments," and Maximilian H. Weinberg, "Recent Advances in Neuropsychiatry."——A symposium on "Spastic Paralysis (Cerebral Birth Paralysis)" was presented before the Pittsburgh Orthopedic Club April 26 by Drs. Paul Titus, Samuel S. Allen Jr., John A. Heberling and Jessie Wright.

SOUTH CAROLINA

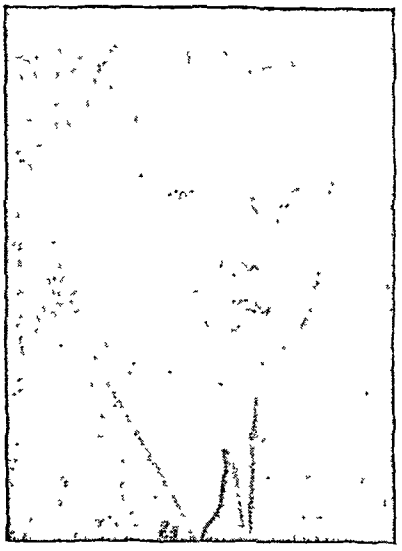
State Medical Election.—Dr. William L. Pressly, Due West, was chosen president-elect of the South Carolina Medical Association at the annual meeting in Spartanburg April 13 and Dr. Douglas Jennings, Bennettsville, was installed as president. Dr. Clough H. Blake, Greenwood, was elected vice president and Dr. Edgar A. Hines, Seneca, was reelected secretary for his thirtieth year. The 1940 meeting will be held in Charleston.

TENNESSEE

State Medical Election.—Dr. William O. Baird, Henderson, was elected president of the Tennessee State Medical Association at the annual meeting in Jackson April 14. Vice presidents elected were Drs. Julian G. Price, Dyersburg; Robert B. Gaston, Lebanon, and James E. Carson, Maryville. The 1940 meeting will be in Chattanooga.

Society News.—Dr. Virgil P. W. Sydenstricker, Augusta, Ga., addressed the Southern Interurban Clinicians Club in Nashville recently on "Hemolytic Icterus Following Splenectomy for Thrombocytopenic Purpura"; Dr. Sydenstricker was president of the club during 1938.——Drs. Henry L. Douglass and Robert H. Williams addressed the Nashville Academy of Medicine and Davidson County Medical Society, Nashville, March 28, on "Exstrophy of the Bladder" and "Results of Fever Therapy at Vanderbilt Hospital" respectively.——Drs. Henry G. Rudner and Robert L. Sanders, Memphis, Tenn., addressed the Dyer-Lake-Crockett Counties Medical Society, Dyersburg, March 1 on medical and surgical management, respectively, of common diseases of the colon, and Dr. Edward B. Smythe, Tiptonville, on "Henoch's Purpura."

GENERAL



Society News.—The eighteenth annual convention of the American Physiotherapy Association will be held at the Hotel Cosmopolitan, Denver, June 25-30.——Dr. Irvin Abell, Louisville, Ky., President of the American Medical Association, was chosen president-elect of the Southeastern Surgical Congress at the annual meeting in Atlanta, Ga., in March. Dr. Grady E. Clay, Atlanta, was elected vice president and Dr. Benjamin T. Beasley, Atlanta, reelected secretary. Dr. Robert L. Sanders, Memphis, Tenn., became president for the coming year.

Hospital in India Needs Woman Physician.—The Woman's Hospital at Gauhati, Assam, in northeastern India is in urgent need of a woman physician, according to an announcement. The hospital has forty-five beds and during 1938 cared for 700 inpatients. Those interested should be able to do surgical work. There are two American nurses on the staff, two Indian women physicians, eight Indian staff nurses and twenty-six nurses in the training school. Laboratory and x-ray equipment are available. The hospital is under the Woman's American Baptist Foreign Mission Society. Applications and inquiries may be addressed to the Christian Medical Council, 156 Fifth Avenue, or to Miss Hazel F. Shank, 152 Madison Avenue, New York.

Medal Awarded to Eve Curie.—The Clement Cleveland Medal was presented to Eve Curie, Paris, France, at a dinner given by the New York City Cancer Committee at the Cos-

mopolitan Club April 18. In making the presentation, Dr. Francis Carter Wood, director of the Crocker Institute of Cancer Research, Columbia University, stated "Those in charge of this award, to be given to one who has achieved most during the year in our contest against cancer, are unanimously of the view that it should be given to the author of the 'Life of Madame Curie'—your rare achievement in writing so superb a life of your mother." According to the New York *Times*, this was the first foreign award of the Clement Cleveland Medal for distinguished service to public education on cancer control.

Young Physician Disappears.—Dr. Runyon H. Irvin, Mt. Vernon, Ill., disappeared from his home March 31. A reward is offered by the chief of police of Mt. Vernon and by his father, Mr. Grant Irvin, telephone 1015, Mt. Vernon, for information as to his whereabouts. Dr. Irvin is 31 years old, 5 feet 11 inches tall, weighs 150 pounds, has a fair complexion, blue eyes, light hair, white teeth with gold fillings. He was wearing a long light gray overcoat, a brown suit, a dark gray hat and black shoes size 11. He is said to be well mannered and genial and does not use tobacco or intoxicants. He had recently suffered a nervous breakdown. Any message concerning him should be telephoned collect to his parents.

Fellowships Awarded.—Twelve fellowships in the medical sciences, including three renewals, for study in the United States and abroad during the year 1939-1940, were awarded at the February meeting of the medical fellowship board of the National Research Council, Washington, D. C. A list of the successful candidates and institutions where they are to work follows:

Philip P. Cohen (renewal), University of Sheffield, England.
Thomas Harrison Davies (renewal), California Institute of Technology.
Victor M. Emmel, Yale University Medical School.
Dr. Alto E. Feller, Harvard Medical School, Boston.
Arden Howell, Duke University, Durham, N. C.
Fremont Ellis Kelsey, University of Pittsburgh.
Dr. Abe Ravin, Harvard, Boston.
Joseph Shack, Johns Hopkins University School of Medicine, Baltimore.
William M. Wallace, Harvard, Boston
Wilfred W. Westerfeld (renewal), Eidgenossische Technische Hochschule, Zurich, Switzerland.
Richard Winzler, University of Stockholm, Sweden.
Dr. William Barry Wood Jr., Harvard.

American Heart Association.—The fifteenth scientific session of the American Heart Association will be held in St. Louis at the Hotel Jefferson May 12-13. The Lewis A. Conner lecture will be delivered by Dr. Harry Goldblatt, Cleveland, on "Experimental Observations on the Pathogenesis and Treatment of Essential Hypertension." Dr. Cecil K. Drinker, Boston, will present the George Brown Memorial Lecture on "Physiological Considerations of the Formation and Movements of Lymph." Other speakers on the program include:

Drs. James Allen Kennedy, Nashville, Tenn., and Charles Sidney Burwell, Boston, Factors in the Circulatory Changes Associated with Pregnancy.
Dr. Henry A. Schroeder, New York, Importance of Restriction of Salt as Compared to Water in Cardiac Failure.
Bradley M. Patten, Ph.D., Ann Arbor, Mich., Microcinematographic and [illegible] of the First Heart Beats and the Begir [illegible] Living Embryos.
Dr. Do [illegible] im, M.B., and Dr. Charles H. Best, Toronto, Effect of Heparin in the Prevention of Thrombosis Experimentally Produced in Various Blood Vessels.
Dr. Reginald H. Smithwick, Boston, Immediate Effects and Late Results of Sympathetic Denervation of the Upper Extremity by Preganglionic Section.

Alumni Meetings in St. Louis.—The Missouri Medical College, class of 1899, will have a table at the Washington University Medical School Alumni banquet May 17 in the Gold Room of the Hotel Jefferson during the Annual Session of the American Medical Association in St. Louis.——The Phi Delta Epsilon fraternity will hold a dinner dance at the Hotel Chase May 17 at 7:30. Additional information may be obtained from Dr. Sam D. Soule, 4500 Olive Street, St. Louis.——Alumni of Northwestern University Medical School, Chicago, are holding a dinner in the Hotel Jefferson, St. Louis, May 17, at 6:30 p. m. Dr. George F. Rendelman, St. Louis, class of 1915, is chairman in charge. Dr. John A. Wolfer, Chicago, class of 1908, is president of the medical division of Northwestern University Alumni Association.——A dinner will be held in the main dining room of the Hotel Statler, Ninth Street and Washington Avenue, St. Louis, Wednesday evening May 17 at 7 o'clock by the Jefferson Medical College Alumni, for which all Jefferson alumni are requested to make reservations at convention headquarters. The dinner will be à la carte. Dr. Theodore P. Brookes, 1650 South Grand Boulevard, St. Louis, is chairman of the Alumni and Fraternity Reunion Committee.

FOREIGN

Dr. Loewi in Belgium.—Information has been received that Dr. Otto Loewi, formerly of the University of Graz, Austria, and co-winner of the Nobel Prize in medicine and physiology in 1936, has been released from Germany. He may be addressed in care of Club de la Fondation Universitaire, Rue d'Egmont, Brussels, Belgium. Before being released he was deprived of all his property, both inside and outside of Germany, including his Nobel Prize money, which had never been in Germany or Austria. His wife is still detained in Germany.

International Tuberculosis Conference.—The Eleventh Conference of the International Union Against Tuberculosis will be held in Berlin September 16-20 under the presidency of Prof. Lopo de Carvalho, Lisbon, Portugal. The subjects to be discussed are: "The Problem of the Virulence of the Tubercle Bacillus," "The Value of Systematic Examinations for the Detection of Tuberculosis in Subjects Over 15 Years of Age" and "The Rehabilitation of the Tuberculous." Speakers from the United States include Dr. Kenneth C. Smithburn, New York; Dr. Willard B. Soper, New Haven, Conn., and Dr. Henry Kennon Dunham, Cincinnati. Correspondence should be addressed to the Konferenzleitung der XI Konferenz der Internationalen Vereinigung zur Bekampfung der Tuberkulose, Berlin W 62, Einemstrasse 11, Germany.

Government Services

Colonel Magee Named Surgeon General of the Army

Col. James Carre Magee, Medical Corps, U. S. Army, has been appointed surgeon general of the U. S. Army with the rank of major general. He succeeds Major General Charles R. Reynolds, whose term as surgeon general expires May 31. Colonel Magee was born in Ireland in 1883. He graduated at Jefferson Medical College, Philadelphia, in 1905. In 1907 he joined the army as contract surgeon, serving for a time in the medical reserve corps of the army. In 1909 he was commissioned first lieutenant in the medical corps of the army, subsequently advancing through the various grades until 1935, when he was commissioned colonel.

Examination for Appointment in Medical Corps

The War Department announces that an examination will be held July 17-21 to qualify candidates for appointment as first lieutenants in the medical corps, regular army, to fill vacancies occurring during the next fiscal year. Due to the expansion of the air corps and coast defenses with the proportionate increase in officers of the medical corps, it is anticipated there will be considerably more than the usual number of vacancies. The examination is open to all male graduates of acceptable medical schools who have completed one year's internship in an approved hospital and who will not be over 32 years of age at the time it will be possible to tender a commission. It will be conducted by boards of medical officers convened throughout the United States and will consist of a physical examination, a written examination in professional subjects and a determination of the candidate's adaptability for military service. For additional information and application blanks address the Adjutant General, War Department, Washington, D. C. Applications will not be considered after June 30.

LONDON

(From Our Regular Correspondent)

April 8, 1939.

Limitation of Population Without Contraception

The most striking demographic phenomenon of the countries of western Europe is a fall in the birth rate of about 50 per cent in the last sixty years. In England the usually accepted cause is the use of contraceptives, though others, such as the change in the national diet from whole meal to white bread (producing shortage of vitamins B and E), were suggested at a discussion on the subject held at the Royal Society of Medicine (THE JOURNAL, March 19, 1938, p. 908). The use of contraceptives is undoubtedly an important cause, but its numerical importance is not known. In the want of exact knowledge on this point it is of great interest to turn to a neighboring country which shows a similar fall but in which contraception can be practically excluded. Eire is a Roman Catholic country and the people obey the teaching of their church, which condemns contraception. Moreover, the government has made the sale of contraceptives a serious criminal offense. Yet the carefully compiled analysis of the 1936 census, which has just been published, shows a small decline of population. This has not yet occurred in England but is imminent. In the two countries there is a similar decrease in the proportion of the young in the population and increase in the proportion of the old. In Eire, with a population of 3 million, the total decrease since the last census ten years ago is 3,500, but the numbers under the age of 21 years have fallen by 69,000 and under 15 by 47,000. A continuous trend toward an aging population has been in progress since the famine 100 years ago and is partially explained by emigration. The other factor—which indeed is the dominant one of the statistics—is late marriage. Between the ages of 25 and 29 as many as 82 per cent of males are single. This is the highest percentage in Europe and contrasts with 68 per cent in Austria, 47 per cent in England and Wales and 37 per cent in the United States. The percentage of unmarried females and their average age are higher than in most countries. With this handicap it may seem surprising that the decline of population is so small. The explanation is the high degree of fertility of those who do marry, which again is evidence of the absence of contraception. Thus the economic cause, which is limiting population in other western countries, operates, but in a different way.

Regionalization of the Public Health Service

A scheme for regionalization of the public health service has been formulated and in consequence of the international situation is rapidly being brought into force. For this purpose England has been divided into five regions, and a principal regional medical officer has been appointed for each region. He will be assisted by a small team of medical officers selected from the staff of the Ministry of Health. The new arrangement does not involve any substantial alteration in the duties which the medical officers of the department perform at present or in their relations with local authorities, but it is believed that the existence of regional staffs, who will be more familiar with local circumstances and problems than officers stationed permanently at headquarters, will be of great assistance. It is hoped also that local authorities and their officers will find it convenient to be able to refer to principal medical officers in their own regions questions of a medical or quasimedical nature. But there is a still more important reason. The regional scheme is an essential element in the preparations which the ministry is making to provide medical services for a possible national emergency. Its advantages are obvious if an air attack on London should produce any dislocation of the central control. The scheme does not involve any major change in the work of the senior medical officers at the ministry, who are responsible for special services, such as maternity and child welfare and tuberculosis, though it is hoped that they will be relieved of some routine work. In addition to their general duties they will be available for consultation with the regional staffs and, as in the past, with local authorities. The regional staffs have also been selected to make possible some specialization among their personnel. Some time must elapse before the scheme can be brought into full operation, but the urgency is such that it has been brought into force on a provisional basis.

A Zoological Index

The Zoological Society of London announces the approaching completion of the Nomenclator Zoologicus under the editorship of Dr. Sheffield Neave. This great work will be an index of the generic names of all animals. The foundation of modern nomenclature is the tenth edition of the Systema Naturae of Linnaeus, published in 1758. The Nomenclator Zoologicus is an attempt to bring into a single alphabetical arrangement all the names of genera and subgenera published during and since the time of Linnaeus down to 1935. The information contained in the new Nomenclator could be found previously only by searching a large number of publications of which the far more expensive and most ambitious is the Nomenclator Animalium Generum et Subgenerum in course of issue by the Prussian Academy of Science since 1926 and still incomplete, with references only up to 1921. The enormous number of animals which have been and are still being described by science is not generally realized. The new Nomenclature will contain 225,000 generic and subgeneric names, some 5,000 of which are not to be found in any similar work. It is said that some 10,000 new species and 2,000 new genera of insects are described each year. Of the total in the Nomenclator more than half the genera are insects, the mollusks account for 30,000, the arachnids, crustaceans and birds for 10,000 each and the worms for 8,000. The price of the Nomenclator is $31 to subscribers and $42 after publication. It has been made as low as possible and bears little relation to the cost of production.

Chemotherapy Combined with Immunotherapy

Little work has been done on the relative merits of chemotherapy and immunotherapy or on the value of combining them. At the Royal Society of Medicine Prof. Alexander Fleming of the inoculation department of St. Mary's Hospital made a communication on the synergic action of vaccine and serum therapy and on treatment with sulfanilamide and sulfapyridine. He said that it had been shown that the new chemotherapeutic agents had a bacteriostatic rather than a bactericidal action. Their chief result was interference with the growth of organisms, the destruction of which was completed by the natural defensive mechanism of the body. Even in the case of the organism most sensitive—the hemolytic streptococcus—the drug alone did not suffice to destroy it. Immunity could be increased passively by serum therapy or actively by vaccines. The results of combined serum and sulfapyridine were not yet available, but he had carried out experiments in vitro which showed the value of the combination. Antipneumococcic serum was found greatly to increase the antibacterial effect of a blood-sulfapyridine mixture on pneumococci. Several workers had shown that antiserums in conjunction with sulfanilamide had a striking action. The administration of vaccines with the new chemotherapeutic agents had given results far superior to either alone. Fleming described experiments on the mouse and rabbit in which these animals were injected with pneumococcus vaccine and six days later with pneumococci. Vaccine therapy alone, like chemotherapy alone, pro-

duced a diminution in the number of colonies, but only the two combined produced total destruction. There was clinical evidence pointing in this direction, though it was not conclusive. His conclusion was that the new drugs acted on certain sensitive bacteria, retarding or preventing their reproduction, and that then the natural defensive mechanism completed the destruction. The result depended on the sensitiveness of the infecting organisms to the drug and also on the immunity of the patient. This immunity could be increased by serums or vaccines, but the former were available only for certain infections while the latter could now be obtained for almost all bacterial infections.

PARIS

(From Our Regular Correspondent)

April 1, 1939.

Annual Meeting of American Hospital Board

After passing resolutions thanking Mr. E. B. Close for his services, without remuneration, as managing governor of the hospital, attention was called at the annual meeting of the board of governors to the fact that for the first time in the history of the American Hospital of Paris the budget for 1938 had been balanced. The medical, nursing and administration staffs were thanked by the board of governors for their untiring devotion. Services representing an income of more than two million francs (about $55,000) were rendered to part pay and free patients during 1938. In addition to the American resident physician, whose length of service varies from one to three years, the hospital also receives three graduates of American medical schools for one year's service. The nurses' training school was discontinued because of lack of funds a few years ago, but there are seventy graduate nurses from various American and European hospitals.

During the past year, donations amounting to more than 450,000 francs ($13,000) were received. The total number of inpatient days was 32,719, of which 11,260 were ward patient days. On an average forty-one patients were treated daily in the outpatient department.

Radiophotography in the Diagnosis of Tuberculosis

Examination of large groups of persons for pulmonary tuberculosis entails an almost prohibitive expenditure if films are used in every case; hence in France at least it has been necessary to limit examination of the lungs to radioscopy. At the January 31 meeting of the Académie de médecine of Paris a method termed radiophotography as employed at Rio de Janeiro, Brazil, by Dr. Manuel de Abreu was described by Dr. Georges Ronneaux of Paris. Radiophotography, or indirect radiography, consists in simultaneously photographing the thoracopulmonary images as they are observed at radioscopic examination. The camera is similar to the cameras sold everywhere for making cinematographic films. The photographs of the radioscopic images are too small to be studied directly, but they can be examined with the aid of a magnifying glass or can be enlarged for lantern slides or films of adequate dimensions, to be inspected as would be ordinary 14 by 17 inch films of the chest. When these enlargements are compared with the minute images obtained by the cinematograph, it is found that every detail observed during the radioscopic examination is preserved. The advantages of this newer method of radiophotography are that the films can be studied at a time when the radiographer is not engaged in the examination of many persons and that the expense is minimal as compared with that of making a film of every chest. When positive evidence is noted at radioscopic examination, the latter is followed by the older method of exposing the larger films.

Radiophotography is primarily a method to be recommended for the examination of large groups of school children, soldiers, sailors and hospital and industrial personnel and for use in dispensaries for the detection of pulmonary tuberculosis early in its evolution. A number of films were shown by Dr. R- neaux of patients at the Hôpital Cochin of Paris He h perfected an apparatus, termed an oscillostrator, so that t- recently introduced method of tomography, or the study (lesions of the chest in sections (pulmonary stratigraphy), c- be combined with Dr. Manuel de Abreu's method of radiop- tography. With the aid of the oscillostrator, instead of b-- obliged to use seventy-two large films for nine patients, at a- expense of 1,800 francs, he found it necessary to expose on- eighteen large films, of areas which required special study, a- an expense of only 395 francs.

Treatment of Obliterating Arteritis

At the February 28 meeting of the Académie de médecine a paper was read by Dr. Jean Walser and his co-workers in which the results of the treatment with alternate compression and decompression of twelve patients with obliterating arteritis were reported. This method has been extensively used in the United States. A marked improvement was noted in nine patients. The apparatus employed was that of Drs. Rosenfeld and Garsaux, described in the July 7, 1937, *Presse médicale*. No difference in the results was noted so far as sex was concerned. The improvement was especially of a functional character, but little relief of the pain being noted in spite of a progressive diminution of the index. A marked improvement in the trophic changes, especially in the cyanosis, was noted. The authors believe that this method of alternate compression and decompression is an important addition to the treatment of obliterative arteritis.

Incidence of Retroplacental Hemorrhage

According to an article by Drs. Trillat and Magnin in the December 1938 *Revue française de gynécologie*, sixty-six retroplacental hemorrhages were observed in 20,000 deliveries. In fourteen of the sixty-six cases there was an anomalous insertion of the placenta, but clinically these fourteen cases did not differ in any respect from those in which the placental insertion was normal. There are three clinical forms of retroplacental hemorrhage: 1. A mild form of which twenty cases have been observed; the fetus does not die in this form and the extent of separation does not exceed more than half the surface of the placenta. 2. A moderately severe form, with death of the fetus but survival of the mother; there were forty-two cases of this form. 3. The severe form, which is rare, only four cases being observed, with a maternal mortality rate of 25 per cent. Albuminuria was not found in any of the sixty-six cases. The prognosis is far less favorable in multiparas and in general beyond the age of 30 years. The earlier the symptoms appear, the less favorable the prognosis. The total fetal mortality was 66 per cent and it does not appear possible at the present time to lower this high mortality rate. Medical treatment is indicated for the mother. Following artificial rupture of the bag of waters, further obstetric intervention should be undertaken with caution, because of danger of rupture of the uterus. Surgical treatment was never employed by the authors, who believe that it is rarely indicated.

Danger of Epidemics from Spanish Refugees

The French army and public health service deserve credit for the manner in which 400,000 Spanish military and civilian refugees have been vaccinated and cared for in various portions of France. In an article by Dr. Sautet of Marseilles which appears in the February 25 issue of *Presse médicale*, attention is called to the danger that two diseases which are prevalent in Spain and northern Africa, viz.: Spanish recurrent fever and malaria, may be brought into France by the refugees. The incidence of these two forms of infection is small in European France. Spanish recurrent fever is due to Treponema hispanicum and is transmitted to human beings by bites of the ordinary tick and the tick found on dogs. Malarial infection is

especially to be feared in the spring; hence it will be necessary for the French public health service to isolate persons who have had malaria as soon as any signs of recurrence appear.

Twenty-Fifth Anniversary of Biochemical Society

The French Biochemical Society was founded in 1914. To celebrate its twenty-fifth anniversary, a meeting will be held at the Maison de chimie May 26. Two foreign biochemists will read papers at the afternoon session. Professor Thunberg of Sweden will discuss the active role of hydrogen and of water in the phenomena of biologic oxidation, and Professor Polonovski will speak on twenty-five years of biochemistry. Foreign biochemists desiring to attend are asked to write to Mr. René Fabre, 149 rue de Sèvres, Paris.

Protection of Hospitals Against Aerial Attack

The national minister of aviation and commander-in-chief of air forces, Goering, has issued certain rules relative to the structural protection offered by civil and military hospitals and similar institutions against aerial attack. According to the air minister the proper protection of institutions that serve public health can be a vital factor in the capability of a population to resist aerial attack. It is emphasized that, in the choice of the site for a new hospital, possible danger of aerial attack should be considered as well as the hygienic requirements. Larger institutions that serve health should not be erected on sites manifestly vulnerable to aerial attack. Among extremely dangerous locations, the inner zones of cities and thickly built up areas may be reckoned. The total bed capacity of a civilian hospital or similar institution (with the exception of a university clinic) should not exceed 600 beds; military hospitals should not have more than 450 beds. Several smaller establishments at different locations are thus preferable to one large establishment. Adequate structural separation of various parts of an institution offers the best and most effective aerial protection. The pavilion system, however, is not recommended.

Air raid shelters must be constructed for the institution's personnel and patient population; there must also be especially protected emergency operating rooms. Shelters for bedfast patients and their nursing personnel should, if possible, be located in the basement. Separate shelters should be provided for patients with infectious disease. Special stipulations are made for air raid shelters in institutions for children, convalescents and old people. The architectural plans of new buildings are to include ample facilities for protection.

All civil and military hospitals should be inspected to determine whether any are so exposed that in the event of aerial attack the population would have to be evacuated. Hospitals dangerously situated should maintain their present size even if under normal conditions expansion would be demanded; in the course of time they should be torn down. If in any of the extant hospital buildings it is found impossible to provide suitable shelters from aerial attack, either in the basement or on the ground floor, new outbuildings to serve as shelters should be constructed. In such hospitals certain space may be designated within the main building which could be used if an aerial emergency should occur before the regular shelters have been completed..

Debut of Physicians in Domain of Art

"The Doctor as Painter and Sculptor" is the title of an exhibition in Berlin from February 12 to March 12 under the auspices of the Empress Frederick House for Graduate Medical Affairs. Here, for the first time in Germany, physicians have made a public debut in the domain of art. Heretofore many doctors have been known to be endowed with musical and literary talents, a number of doctors have been known who were writers and poets, and there are doctors' orchestras in Berlin, Vienna and Hamburg which have a good reputation. But nothing much has been known with regard to the extent to which physicians are active in the arts of painting and sculpture. Surprisingly, the jury of the exhibition was called on to choose from among 600 works of various kinds, including a number of carvings and chiseled forms. Among the 140 pieces selected for the exhibition, every genre, medium and technic was represented from the woodcut to the etching, from the small aquarelle, through the pastel and tempera to large-scale painting in oil, as well as wood carving and bronze casting. As many sided as the artistic aspect of the exhibition is its personal side. All types of medical men are represented, from the student to the ordinarius, from the country practitioner to the metropolitan specialist. That neurologists possess a special predilection for the brush and palette becomes evident at a first perusal of the catalogue. Virtually all the entries can be considered above the level of average amateur performance and among them are to be found some really fine works of art.

Congress of Roentgenology

The thirteenth National Congress of the Società Italiana of Medical Roentgenology took place recently at Bari with Professor Pietro as president.

HYSTEROSALPINGOGRAPHY

Prof. Armando Rossi, speaker on the first topic, dealt with female sterility, ectopic pregnancy and abortion. He pointed out the clinical and social importance of hysterosalpingography, especially in relation to dermography. He discussed the various causes of female sterility (congenital malformations, insufficient development, tumors and tubal stenosis) and advised the systematic performance of hysterosalpingography on all women who are sterile during the first year of marriage. The main characteristic of ectopic pregnancy is a special function of the uterus with periodic successive phases of contraction and dilatation, predominance of the phases of dilatation and prolonged phases of contraction. According to him, abortion from the so-called unknown causes may be due to (1) abortigenic causes on which the physician is not informed in the given case, (2) anatomic conditions and functional behavior of the uterus or (3) congenital hypoplasia of the female genitalia. Hysterosalpingography has important indications in prevention and treatment of abortion from demographic, social, clinical and medicolegal angles.

RADIOBIOLOGY OF SKIN

Professor Valenti, speaker on the second topic, said that radium and roentgen irradiations on the skin cause direct lesions to cutaneous cells with consequent temporary arrest of the functions of reproduction of the cell or death from necrosis of the nucleus. In the presence of dead cells the reparation of the basal epithelium takes place either by entrance of normal cells in the involved zone or by compensation of connective cells. If the skin is the seat of repeated irradiations in small doses, such as in the case of roentgenologists, trophic cutaneous alterations take place. The reactions of the skin to radium and roentgen irradiations are different in persons who have been previously treated by the same irradiations than in those who have not. The special behavior of the skin in these cases is due to the allergic factor.

IRRADIATIONS ON MEDIASTINUM

Professor Castronuovo pointed out the importance of roentgenology for the diagnosis and treatment of diseases of the mediastinum as well as other diseases related to physical and

psychic constitution. Roentgen irradiations are indicated in the treatment of bronchial asthma, whooping cough and hypertension..

RHEGMOGRAPHY AND STATIGRAPHY

Professors Cignolini and Gilardoni made demonstrations of an apparatus for rhegmography. The technic is original and has a place which is intermediate between seriography and kymography. Professor Vallebona presented a statigraph. Professors Palmieri and Monari reported a procedure for obtaining photographs of fluorescent screen on small x-ray films. The next congress will take place at Pisa with Professor Duranti presiding.

The Treatment of Syphilis

The Warsaw dermatologist Dr. Robert Bernhardt reported recently on the effect of treatment in 592 cases of primary and secondary syphilis. He discussed the question whether antisyphilitic treatment could prevent the development of visceral or nervous syphilitic conditions. Every case was observed for not less than ten years unless visceral or nervous involvement had developed earlier. Some of the cases have been observed since 1900; in many the treatment was started before the discovery of Spirochaeta pallida, arsphenamine treatment and serologic tests. Of the 592 patients, 133 were treated exclusively with mercury compounds, forty with arsenicals and twenty-three with bismuth preparations. A combined treatment with arsphenamine and mercury compounds was used for 271, and in 125 cases arsphenamine and bismuth preparations were used.

With mercury compounds alone, the author says that an effective treatment should consist of from six to nine series of rubs with mercuric ointment. Every series lasts from six to eight weeks, the rubs being performed daily for six days a week and the daily dose being increased from 2.5 to 4 Gm. of mercuric ointment. The dose varies with the general condition of the patient; it is reduced if any complication develops in the gums, kidneys or colon or if a fall in body weight is observed. The treatment has to last from three to five years. While the ratio between the number of good and of ill effects obtained with mercuric treatment was 1 to 1.7, no late syphilitic complications were observed in six of seven adequately treated patients.

In the series of patients treated with arsphenamine or neoarsphenamine alone, the ratio between good and ill effects was but 1 to 9. The author says that arsenical preparations act rapidly and effectively as far as symptomatic treatment of present syphilitic manifestations is concerned. As to prevention of later visceral recurrences, however, no evidence of any favorable influence has as yet been shown.

The treatment with bismuth preparations was effective in preventing later syphilitic complications. Eight of nine patients treated exclusively with adequate doses of bismuth for a sufficient period showed no evidence of such complications. In the entire series of patients treated with bismuth preparations the ratio between good and ill effects was 1 to 0.35. An adequate bismuth treatment should last from two to four years and consist of from five to nine series of from eight to ten weekly injections, each containing 0.2 Gm. of metallic bismuth. The patients treated with bismuth seem to be less disposed to later development of neurosyphilis than those treated with other drugs.

Combined treatment with arsphenamine and mercury showed a ratio between good and ill results of 1 to 1.2. The incidence of good effects was higher if the treatment was adequate. This treatment should consist of simultaneous administration of arsphenamine and a mercury preparation. The doses of each drug should not differ from the effective doses administered when the two are given separately. The same is to be said concerning combined treatment with arsphenamine and a bismuth preparation. In this series of cases the ratio between good and ill effects was 1 to 0.78. The results of combined treatment with arsphenamine and mercury and with arsphenamine and bismuth do not differ distinctly.

In conclusion, the author says that arsphenamine has not fulfilled expectations in the prevention of late visceral or nervous manifestations of syphilis.

Relation of Hypoglycemia to Hypotonia

Dr. H. Fiszel published a paper on carbohydrate metabolism in hypotonic states. He focused attention on the striking resemblance of the clinical picture of constitutional hypotonia to hypoglycemic states, which could be observed in hyperinsulinism as well as in hypoglycemia provoked for therapeutic or experimental purposes. Thus constitutional hypotonia seems to be related to hypoglycemic conditions. To throw light on this problem the author studied the blood sugar content in primary and secondary hypotonia, particularly in the glycemic curve before and after oral administration of 50 Gm. of dextrose. The research was carried out with forty patients with primary, i. e. constitutional, hypotonia as well as with subjects with secondary hypotonia, i. e. hypotonia due to such factors as heart failure and infectious diseases. There was a great difference between the shapes of the curves obtained in the two conditions. In comparison with normal records, the curve in constitutional hypotonia has been characterized by an initial subnormal level of blood sugar, an early and relatively low peak and a rapid drop, with a final deep hypoglycemic depression. In secondary hypotonia too initial hypoglycemia was present, but the peak of the curve was much higher and delayed and no final subnormal depression was shown. In some instances, in which the clinical differentiation between primary and secondary hypotonia was difficult, the curve had a medium or fairly normal shape.

The author says that there is in constitutional hypotonia a tendency to an absolute increase in the tonus of the vagal system and of the endocrine glands synergistic with insulin, while in secondary hypotonia the increase in the tonus of the vagus-insulin is relative and due to a decrease in the tonus of the sympathetic adrenal system. Further research should show whether the glycemic curve might aid in differentiating between primary and secondary hypotonia.

A Rheumatism Institute

The health authorities have decided to establish a Polish rheumatism institute to insure research on rheumatism and postgraduate education of physicians in rheumatology. There has been as yet no such institution in Poland.

Marriages

FREDERICK RUSSELL HASELTON, Lieutenant Commander, U. S. Navy, to Mrs. Ebba Hovey Hall at Great Lakes, Ill., April 14.

DALLAS NORMAN THOMPSON to Mrs. Emmie de L. Hambaugh Robinson, both of Elberton, Ga., March 18.

ROLF ANDREAS QUISLING to Miss Marie J. Sweeney, both of Madison, Wis., in Dubuque, Iowa, March 16.

SAUL RICHARD KAPLAN, Brooklyn, to Miss Reva Syril Stein of Fayetteville, N. C., March 12.

MICHAEL A. SALEEBY, Dillon, S. C., to Miss Mary G. Saleeby of Florence, March 22.

MORTON SELWYN KAUFMAN to Miss Janice Loeb, both of Washington, D. C., March 30.

RICHARD O. FLETT to Miss Alfreda Sharpe, both of Detroit, in Buffalo, March 21.

Deaths

William Edward Morgan, Chicago; Chicago Medical College, 1882; prosector in anatomy, 1881-1882, demonstrator in anatomy in 1885, demonstrator in operative surgery in 1887, professor of surgical anatomy and operative surgery in 1892, professor of clinical surgery, 1902-1920, and in 1924 was appointed medical counselor at his alma mater; professor of general and clinical surgery, Loyola University School of Medicine, 1920-1929, and since 1929 professor emeritus; past president of the Chicago Surgical Society; formerly on the staffs of the Mercy Hospital, Englewood Hospital, German Deaconess Hospital, Provident Hospital, Washington Park Hospital and the Jackson Park Hospital; aged 80; died, April 25, of chronic myocarditis and arteriosclerosis.

Arthur Vallée, Quebec, Que., Canada; Laval University Faculty of Medicine, Quebec, 1905; secretary and professor of pathological anatomy at his alma mater; from 1908 to 1912 director of the Municipal Laboratory, after serving as laboratory head at Hotel Dieu Hospital; in 1916 president of the eighth Congress of French-Speaking Physicians of America; was created a Chevalier of the Legion of Honor by the French Government during the jubilee of King George V and again at the coronation of King George VI.; member of the Royal Society of Canada, French Association for Study of Cancer, Royal College of Physicians and Surgeons of Canada and other medical societies; aged 56; died, January 8.

Leo Steiner, Chicago; Jenner Medical College, Chicago, 1906; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; member of the Illinois State Medical Society; instructor in medicine, 1911-1913, instructor in materia medica, 1913-1914, associate professor of materia medica and therapeutics, 1914-1915, and professor of materia medica and therapeutics, 1915-1916, Bennett Medical College; formerly superintendent of the Illinois Eye and Ear Infirmary; aged 55; died, January 7, of carcinoma of the colon with metastases to the liver.

Arthur Melville Shrady ⊕ New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1893; instructor in physical diagnosis, Jan. 1, 1902, to June 30, 1907, chief of clinic and instructor in hydrotherapy, July 1, 1907, to June 30, 1908, and instructor in hydrotherapy, July 1, 1908, to June 30, 1913, at his alma mater; served in various capacities on the staffs of the Seton Hospital, Harlem Hospital, Herman Knapp Memorial Eye Hospital and the Harlem Eye, Ear and Throat Hospital; aged 69; died, January 14, of heart disease.

Alexander John MacKenzie, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1900; fellow of the American College of Physicians; formerly senior demonstrator in medicine at his alma mater; president of the Ontario Medical Association and past president and councilor of the Toronto Academy of Medicine; served during the World War; for many years physician to the Upper Canada College; on the staff of St. Michael's Hospital; aged 63; died, March 3.

Lewis Cass Tisdale ⊕ Milwaukee; Wisconsin College of Physicians and Surgeons, Milwaukee, 1901; formerly associate clinical professor of surgery at Marquette University School of Medicine; for many years chief of staff at Misericordia, Deaconess, Mount Sinai and the old Trinity Hospital and a member of the consulting staff of the old Johnston Emergency Hospital; aged 60; died, January 12, of hypertensive cardiovascular disease and cerebral hemorrhage.

John David Thomas, West Rupert, Vt.; University of Vermont College of Medicine, Burlington, 1916; member of the Vermont State Medical Society; served during the World War; on the staffs of the Putnam Memorial Hospital, Bennington, Mary McClellan Hospital, Cambridge, N. Y., Emma Laing Stevens Hospital, Granville, N. Y.; aged 48; died, January 31, of coronary occlusion and arteriosclerosis.

Vard Houghton Hulen, San Francisco; College of Physicians and Surgeons of Chicago, 1887; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1888; in 1911 member of the House of Delegates of the American Medical Association; fellow of the American College of Surgeons; aged 73; died, January 14, of chronic myocarditis and cerebral thrombosis.

William Vaughn Stanfield, Attica, Ind.; Medical College of Indiana, Indianapolis, 1904; bank president; formerly county health officer; served during the World War; at one time member of the city council, county board of health and chairman of the board of health of Attica; aged 62; died, January 7, in the Methodist Hospital, Indianapolis, of coronary thrombosis.

Cassius M. C. Willcox, Kirksville, Mo.; College of Physicians and Surgeons, Keokuk, Iowa, 1891; member of the Missouri State Medical Association; served during the World War; formerly county coroner, health officer and county physician, and member of the state legislature; aged 68; died, January 24, of carcinoma of the throat.

Frederick Charles Steinmetz, New York; Columbia University College of Physicians and Surgeons, New York, 1912; member of the American Urological Association; a member of the staff of the department of urology, James Buchanan Brady Foundation of the New York Hospital; aged 52; died, January 22, of heart disease.

John Fulton Roe, Los Angeles; Rush Medical College, Chicago, 1899; fellow of the American College of Surgeons; formerly surgeon to St. Joseph's Hospital, Denver, and chief surgeon to the Denver and Rio Grande Western Railroad System; aged 66; died, January 29, of hypertension and arteriosclerosis.

J. A. E. Beaudoin, Montreal, Que., Canada; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University at Montreal, 1892; formerly governor of the College of Physicians and Surgeons of the Province of Quebec and of Notre Dame Hospital; aged 73; died, January 7.

Frederick Josias Wurtele, North Platte, Neb.; University and Bellevue Hospital Medical College, New York, 1906; member of the Nebraska State Medical Association; served during the World War; aged 61; died, January 17, in the Lincoln (Neb.) General Hospital, of cerebral hemorrhage.

Wilmot Edwin Patterson ⊕ Westbrook, Minn.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1906; past president of the Southwestern Minnesota Medical Society; aged 56; died, January 15, in Slayton, of hemolytic streptococcic throat infection and septicemia.

Charles Joshua Tucker ⊕ Rochester, N. Y.; University of the City of New York Medical Department, 1883; veteran of the Spanish-American War; on the staff of St. Mary's Hospital; aged 79; died, January 25, of hypertensive heart disease and cerebral hemorrhage.

Robert Lee Tye ⊕ McDonough, Ga.; Bellevue Hospital Medical College, New York, 1885; past president of the Henry County Medical Society; aged 73; was drowned, January 8, when his automobile went over a bridge and pinned him down in 3 feet of water.

Lewis Edward Turrentine, Tahoka, Texas; Southwestern University Medical College, Dallas, 1909; member of the State Medical Association of Texas; county health officer; aged 53; died, January 29, in a hospital at Lubbock of acute myocarditis and pneumonia.

Edgar Eginton Stewart Jr., New York; Columbia University College of Physicians and Surgeons, New York, 1936; aged 29; died, January 16, in the Charles Es'Dorn Hospital, Walterboro, S. C., of injuries received in an automobile accident.

Robert Emmett Sylverstein ⊕ Tylertown, Miss.; Tulane University of Louisiana School of Medicine, New Orleans, 1898; formerly mayor; on the staff of the Tylertown Hospital; aged 71; died, January 2, of heart disease and hypernephroma.

Given Addison Light, Salt Lake City; Georgetown University School of Medicine, Washington, D. C., 1906; member of the Utah State Medical Association; served during the World War; aged 61; died, January 11, of coronary disease.

William Mannen Young, Bloomington, Ill.; Eclectic Medical Institute, Cincinnati, 1897; member of the Illinois State Medical Society; on the staffs of St. Joseph's Hospital and Mennonite Hospital; aged 71; died, January 19, of heart disease.

David W. Reid, Jacksonville, Ill.; Chicago Homeopathic Medical College, 1889; member of the Illinois State Medical Society; on the staff of the Passavant Memorial Hospital; aged 83; died, January 15, of bilateral bronchopneumonia.

Charles Whelan, Washington, D. C.; Medical College of Alabama, Mobile, 1896; a member of the United States Board of Parole, Department of Justice; aged 65; died, January 28, in the Garfield Hospital of cerebral hemorrhage.

Allen Gano Wainright, Tulsa, Okla.; Washington University School of Medicine, St. Louis, 1902; member of the Oklahoma State Medical Association; served during the World War; aged 59; was shot and killed in January.

Louis Severin, Bluffton, Ind.; Miami Medical College, Cincinnati, 1899; past president of the Wells County Medical Society; formerly city and county health officer; aged 68; died, January 23, of a self-inflicted bullet wound.

Alexander Augustus Sizer, Schuyler, Va.; University College of Medicine, Richmond, 1899; member of the Medical Society of Virginia; served during the World War; aged 68; died, January 10, of cerebral hemorrhage.

John J. Carmody, Huntington, Mass.; St. Louis College of Physicians and Surgeons, 1924; served during the World War; aged 60; died, January 20, in the Mercy Hospital, Springfield, of influenza and coronary artery disease.

Le Roy Albert Woodward ⊕ Worcester, Mass.; Tufts College Medical School, Boston, 1914; on the staff of the Harvard Private Hospital; aged 56; died, January 22, of lobar pneumonia and pneumococcic meningitis.

Philippe Richer, Montreal, Que., Canada; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1907; aged 55; was found dead in January of poison, self administered.

John Irwin Taylor, Elizabethtown, Ky.; University of Louisville School of Medicine, 1918; member of the Kentucky State Medical Association; aged 45; died, January 27, in the Baptist Hospital, Louisville, of uremia.

Abraham Benjamin Grossman, Cleveland; Western Reserve University School of Medicine, Cleveland, 1914; served during the World War; aged 49; died, January 10, in Miami Beach, Fla., of coronary thrombosis.

Harry Claucet Payne, Paris, Mo.; University of Missouri School of Medicine, Columbia, 1903; member of the Missouri State Medical Association; aged 59; died, January 12, of carcinoma of the colon with metastases.

Paul Jerome Todd, Canton, China; Kansas Medical College, Medical Department of Washburn College, Topeka, 1902; fellow of the American College of Surgeons; aged 65; died, January 16, of coronary thrombosis.

George W. Middleton, Salt Lake City; University of Louisville (Ky.) Medical Department, 1894; member of the Utah State Medical Association; formerly mayor of Cedar City; aged 72; died, Dec. 3, 1938.

Frank Edward Schram ⊕ Chicago; Chicago College of Medicine and Surgery, 1915; served during the World War; aged 49; died, January 16, in St. Luke's Hospital following an operation for acute appendicitis.

James Bonney Sudduth, Clayton, Mo.; Barnes Medical College, St. Louis, 1904; member of the Missouri State Medical Association; formerly health commissioner; aged 82; died, January 28, of arteriosclerosis.

Clarence A. Wells ⊕ Quincy, Ill.; Missouri Medical College, St. Louis, 1897; aged 68; on the staffs of the Blessing Hospital and St. Mary's Hospital, where he died, January 15, of injuries received in a fall.

Adolph Reinhardt Wittman, Merrill, Wis.; Rush Medical College, Chicago, 1888; formerly mayor, health commissioner and member of the board of education; aged 79; died, January 11, of cerebral hemorrhage.

Alfred Edward Oakes, Elizabeth, N. J.; University and Bellevue Hospital Medical College, New York, 1913; served during the World War; aged 52; died, Dec. 20, 1938, in the Alexian Brothers Hospital.

Hugh Morrow, Patton, Pa.; College of Physicians and Surgeons, Baltimore, 1908; aged 63; died, January 9, in the Miners' Hospital of Northern Cambria, Spangler, of chronic nephritis and myocarditis.

John Shaw Gibson, Gibson, N. C.; University of Maryland School of Medicine, Baltimore, 1905; member of the Medical Society of the State of North Carolina; aged 59; died, January 24, of coronary occlusion.

Darwin Schott, Champaign, Ill.; Homeopathic Medical College of Missouri, St. Louis, 1903; served during the World War; aged 58; died, January 30, in the Burnham City Hospital of cirrhosis of the liver.

Randolph Moore Gilliam, Chicago; University of Virginia Department of Medicine, Charlottesville, 1919; aged 43; died, January 14, in the University Hospital, Charlottesville, Va., of rheumatic heart disease.

Henry Augustus Kling, Flint, Mich.; Eclectic Medical Institute, Cincinnati, 1906; served during the World War; aged 65; died, January 24, in St. Joseph Mercy Hospital, Pontiac, of cerebral hemorrhage.

Abraham Mintz, Newark, N. J.; Rush Medical College, Chicago, 1931; member of the Medical Society of New Jersey; aged 34; died in January at the Presbyterian Hospital of chronic myelogenous leukemia.

Harry Webster Powers, Amherst, Ohio; Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1886; aged 74; died, January 16, of cerebral hemorrhage.

Richard George Tietze Jr. ⊕ Winter Haven, Fla.; Long Island College Hospital, Brooklyn, 1936; aged 28; died, January 5, in a hospital at Lakeland of injuries received in a motorcycle accident.

James Carroll Patterson ⊕ Marengo, Iowa; John A. Creighton Medical College, Omaha, 1910; past president of the Iowa County Medical Society; aged 58; died, January 18, of lobar pneumonia.

Edward Elisha Pierce, Exeter, R. I.; Harvard University Medical School, Boston, 1890; member of the Rhode Island Medical Society; aged 82; died, January 28 in Providence, of coronary occlusion.

William Cabell Rives, Washington, D. C.; University of the City of New York Medical Department, 1877; member of the Medical Society of the District of Columbia; aged 88; died, Dec. 17, 1938.

Charles F. Marston, Providence, R. I.; College of Physicians and Surgeons, Baltimore, 1888; aged 74; died, January 3, in the Rhode Island Hospital of coronary thrombosis and prostatic hypertrophy.

Henry Justin Roddy Jr. ⊕ Lancaster, Pa.; Jefferson Medical College of Philadelphia, 1925; served during the World War; aged 41; died, January 11, of illuminating gas poisoning, self administered.

Theodore Dodd ⊕ Steubenville, Ohio; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1907; on the staff of the Gill Memorial Hospital; aged 71; died, Dec. 22, 1938.

Edwin Tracy Rhodes ⊕ York, Pa.; University of Rochester School of Medicine, 1935; aged 28; died, January 26, in the Bryn Mawr (Pa.) Hospital of influenza, pneumonia and encephalitis.

Joseph Marshall Reed, Pittsburgh; Medico-Chirurgical College of Philadelphia, 1904; served during the World War; aged 61; died, January 30, in St. Petersburg, Fla., of cerebral hemorrhage.

George L. McLaughlin, Chicago; Rush Medical College, Chicago, 1900; member of the Illinois State Medical Society; aged 63; died, January 18, in Rochester, Minn., of carcinoma of the colon.

George B. McCutcheon, Detroit; Michigan College of Medicine, Detroit, 1883; Detroit Medical College, 1885; aged 81; died, January 13, of hypertrophy of the prostate and fracture of the hip.

Robert B. South, Rea, Pa.; Baltimore Medical College, 1896; aged 72; died, Nov. 21, 1938, in the Mercy Hospital, Pittsburgh, of hypertensive heart disease, nephritis and diabetes mellitus.

Lyle F. Hansbrough ⊕ Front Royal, Va.; University of Virginia Department of Medicine, Charlottesville, 1901; aged 59; died, January 22, of acute nephritis and hypertensive heart disease.

Charles A. Paddock, Portland, Ind.; Physio-Medical College of Indiana, Indianapolis, 1901; formerly mayor, city and county health officer; aged 64; died, January 18, of heart disease.

Clark L. Phillips, Superior, Neb.; University of Nebraska College of Medicine, Omaha, 1912; aged 53; died, January 28, at the Hastings State Hospital, Ingleside, of coronary thrombosis.

Frederick Almon Steele, Half Moon Bay, Calif.; University of Vermont College of Medicine, Burlington, 1884; aged 74; died, January 18, of prostatic hypertrophy with obstruction.

Bernhard Kugelmann ⊕ New York; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1923; aged 38; died, Dec. 24, 1938, in the Wickersham Hospital.

Robert Nathaniel Cox, Verdi, Va.; Bennett Medical College, Chicago, 1914; aged 60; died, January 28, in the Holston Valley Community Hospital, Kingsport, Tenn., of pneumonia.

Fred L. Murdock, Manhattan, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1905; also a dentist; aged 72; died, January 12, of diabetes mellitus.

Clark Edwin Sargent, Detroit; Rush Medical College, Chicago, 1895; aged 71; died, January 25, in the Providence Hospital of uremia, diabetes mellitus and chronic nephritis.

Ubert Conrad Vincent, New York; University of Pennsylvania School of Medicine, Philadelphia, 1918; formerly on the staff of the Harlem Hospital; aged 46; died, Dec. 18, 1938.

John Jay Waite, Deerfield, Ohio; Cleveland Homeopathic Medical College, 1900; member of the Ohio State Medical Association; aged 78; died, January 26, of heart disease.

Dorothea Willson Dekau Palamountain, Oakland, Calif.; Cooper Medical College, San Francisco, 1905; formerly physician for the city public schools; aged 57; died, January 3.

Owen G. Blackwell, Pine Bluff, Ark.; Tulane University of Louisiana School of Medicine, New Orleans, 1901; member of the Arkansas Medical Society; aged 65; died, January 6.

Charles Willis Duffin, Guttenberg, Iowa; Rush Medical College, Chicago, 1881; member of the Iowa State Medical Society; aged 79; died, January 19, of coronary sclerosis.

Donald Walter McKay, Nelson, B. C., Canada; University of Toronto Faculty of Medicine, 1918; L.R.C.P., London, M.R.C.S., England, 1922; aged 44; died, Dec. 28, 1938.

Earnest L. Meredith, Omaha; Barnes Medical College, St. Louis, 1909; aged 54; died, January 27, in the Immanuel Hospital of Hodgkin's disease and bronchopneumonia.

John Mair Robertson, Vancouver, B. C., Canada; L.R.C.S., Edinburgh, Scotland, 1882; University of Glasgow Medical Faculty, 1883; aged 80; died, Dec. 28, 1938.

James N. Kirk, Eagle Lake, Maine; Jefferson Medical College of Philadelphia, 1889; aged 71; died, January 16, in Roanoke, Va., of perinephric abscess and stone.

Charles Campbell Stanton, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1902; aged 60; died, January 11, of a self-inflicted bullet wound.

John Forster Orr, Chicago; Victoria University Medical Department, Coburg, Ont., Canada, 1886; aged 80; died, January 8 of myocarditis and arteriosclerosis.

Martin Lawson Smail ⊕ New London, Conn.; University of Vermont College of Medicine, Burlington, 1893; aged 71; died, January 21, of chronic myocarditis.

Matthew Reed McBurney, Los Angeles; Hahnemann Medical College and Hospital of Philadelphia, 1899; aged 68; died, January 15, of chronic myocarditis.

John Tazewell Nolen ⊕ Poca, W. Va.; University College of Medicine, Richmond, 1910; aged 54; died, January 13, in a hospital at Charleston of myocarditis.

Edward Olinger Wilson, Madison, Neb.; John A. Creighton Medical College, Omaha, 1909; aged 59; died, January 9, in Bluebell, S. D., of heart disease.

Allard S. Lewis, Green Sea, S. C.; Baltimore University School of Medicine, 1897; aged 68; died, January 17, of coronary thrombosis and hypertension.

Peter Wesley Byers, Arcanum, Ohio; Medical College of Ohio, Cincinnati, 1900; formerly member of the board of education; aged 74; died, Dec. 25, 1938.

Benners Simpson Smith, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1912; aged 52; died, January 3, of chronic nephritis.

Joseph Scholfield Brooks, San Francisco; Hahnemann Hospital College of San Francisco, 1894; aged 66; died, January 22, of intestinal obstruction.

Frederick F. Zelle ⊕ St. Louis; Washington University School of Medicine, St. Louis, 1906; aged 59; died, January 19, in the De Paul Hospital.

Durand W. Youngblood, Greenville, S. C.; College of Physicians and Surgeons, Baltimore, 1886; aged 81; died, January 9, of coronary occlusion.

John F. Courtney, Joliet, Ill.; Chicago Homeopathic Medical College, 1894; member of the Illinois State Medical Society; aged 77; died, Dec. 27, 1938.

William Henry Vose, Long Beach, Calif.; Colorado School of Medicine, Boulder, 1897; served during the World War; aged 69; died, January 14.

John Mathew Wells ⊕ Bristow, Okla.; University of Nashville (Tenn.) Medical Department, 1909; aged 63; died, January 25, of pneumonia.

Thomas L. Nutter, Belle, W. Va.; Louisville (Ky.) Medical College, 1898; aged 66; died, January 16, in a hospital at Charleston of myocarditis.

Placido Venuto ⊕ Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1934; aged 34; died, January 15, of bronchopneumonia.

William H. Mudge, Port Tampa City, Fla. (licensed in Florida in 1903); aged 77; died, January 21, of cerebral hemorrhage and hypertension.

Charles S. Stewart, Amite, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1884; aged 78; died in December 1938.

Perry Norton Whitney, Arkansas City, Kan.; Eclectic Medical Institute, Cincinnati, 1890; aged 82; died, Dec. 6, 1938, in the Mercy Hospital.

H. Orrahood, Big Isaac, W. Va. (licensed in West Virginia, by years of practice); aged 90; died, January 29, of cerebral hemorrhage.

George W. Patchen, Melbourne, Fla.; Chicago Homeopathic Medical College, 1893; aged 67; died, January 8, of coronary thrombosis.

Clinton C. Hall, North East, Pa.; College of Physicians and Surgeons, Baltimore, 1884; aged 79; died, January 9, of coronary thrombosis.

Armon C. Spooner, Spirit Lake, Idaho; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1905; aged 63; died, Dec. 31, 1938.

Samuel Perrin Rich, Tacoma, Wash.; Cincinnati College of Medicine and Surgery, 1902; aged 64; died January 11, of coronary sclerosis.

Robert John Kincaid, Mars Hill, Maine; Medical School of Maine, Portland, 1894; aged 75; died, January 1, of cerebral hemorrhage.

Eugene Y. Willis ⊕ Culpeper, Va.; Medical College of Virginia, Richmond, 1903; aged 60; died, January 5, of cerebral hemorrhage.

Albert Edward Webb, Salem, Mass.; Tufts College Medical School, Boston, 1910; aged 64; died, January 11, in the Salem Hospital.

James Barna Witherington, Munford, Tenn.; Vanderbilt University School of Medicine, Nashville, 1878; aged 84; died, Dec. 22, 1938.

Jacob C. Fults, Waterloo, Ill.; St. Louis Medical College, 1885; aged 77; died, January 30, at Shelbyville, Ind., of a cerebral hemorrhage.

Taylor Russell Baldridge, Dayton, Ohio; Medical College of Ohio, Cincinnati, 1888; aged 77; died, January 22, of cerebral hemorrhage.

William O'Connor, Paterson, N. J.; Albany (N. Y.) Medical College, 1914; aged 65; died, January 30, of cerebral hemorrhage.

Raymond Reed Roberts, Lawrenceville, Ga.; Emory University School of Medicine, Atlanta, 1922; aged 42; died, January 5.

James William McAdow, De Kalb, Mo.; University Medical College of Kansas City, 1908; aged 55; died, January 8, of teratoma.

Arthur Henry Orcutt ⊕ Oakland, Calif; University of Illinois College of Medicine, Chicago, 1918; aged 46; died, Dec. 12, 1938.

William Gibson Hulme, Danville, Ga.; Hospital Medical College, Atlanta, 1910; aged 49; died, January 7, of angina pectoris.

Hugo von Dessauer, Brooklyn; Long Island College Hospital, Brooklyn, 1896; also a pharmacist; aged 60; died, January 2.

John Rossiter Gleason, Cleveland Heights, Ohio; Homeopathic Hospital College, Cleveland, 1889; aged 77; died, January 30.

Fred S. Brown, Oklahoma City; Missouri Medical College, St. Louis, 1893; aged 65; died, January 16, of cerebral hemorrhage.

David Caw Wilson, Park Hill, Ont., Canada; Trinity Medical College, Toronto, Ont., Canada, 1899; died, Dec. 19, 1938.

John M. Fewkes, Rio Grande City, Texas; Hospital College of Medicine, Louisville, Ky., 1895; aged 70; died in January.

Henry H. Imhofe, Baltimore; Baltimore University School of Medicine, 1893; aged 70; died, January 2, of gastric ulcer.

Roscoe Granville Blanchard ⊕ Dover, N. H.; Medical School of Maine, Portland, 1884; aged 85; died, January 12.

William James Stevenson, Aurora, Ont., Canada; Trinity Medical College, Toronto, 1887; aged 74; died, January 22.

Fred Eugene Ladd, Antrim, N. H.; College of Physicians and Surgeons, Boston, 1902; aged 67; died, Dec. 22, 1938.

Alice Lyon Fitch, Stratford, Conn. (licensed in Connecticut in 1901); aged 60; died, January 30, of arteriosclerosis.

William H. Martin, Carlisle, Ky.; University of Louisville Medical Department, 1889; aged 73; died, January 27.

Guy Frank Rogers, Los Angeles; Toledo (Ohio) Medical College, 1897; aged 65; died, Dec. 29, 1938.

Correspondence

SULFAPYRIDINE

To the Editor:—The February 11 issue of THE JOURNAL contains two original articles dealing with a clinical trial of sulfapyridine, an editorial comment, a report to the Council on Pharmacy and Chemistry, as well as a letter in the correspondence columns. Because my contributions to this subject are generously acknowledged and quoted, you will perhaps allow me space to correct one or two misquotations, as well as to comment on some of the conclusions.

I would refer you in the first place to Dr. Long's, in many ways admirable but nevertheless somewhat pragmatic, pronouncement to the Council on Pharmacy and Chemistry (p. 538). I am there said to have "stated without giving experimental detail that sulfapyridine was also an active chemotherapeutic agent in the treatment of staphylococcic infections." The reference given is to my Bradshaw lecture to the Royal College of Physicians, which in its published form contains two protocols concerning staphylococcic infections, the one detailed and the other composite. Dr. Long also quotes me as stating "that in experimental infections the drug acts by bringing about degenerative changes in the capsular material of the pneumococcus." In the publications to which reference is made, I have gone no further than to record that capsular changes are found during the course of a treated experimental infection. I have most carefully refrained from judging the significance of this capsular change until I had made a considerable study. My conclusions have lately been published (McIntosh, James, and Whitby, L. E. H.: *Lancet* **1**:431 [Feb. 25] 1939). I am surprised that Dr. Long has been unable to confirm my observation "that mice infected with pneumococci and treated with sulfapyridine are immune on recovery to infection with the homologous organisms." This phenomenon, first observed by Buttle (*Proc. Roy. Soc. Med.* **31**:154 [Dec.] 1937) with sulfanilamide and pneumococci, has in my own hands been demonstrated so frequently and with such constancy that it has formed the basis for observations concerning the mode of action of sulfanilamide derivatives.

It is unfortunate that Dr. Long's deductions should precede the publication of his experimental protocols; without these one can neither make extensive comment nor criticize the technic on which his conclusions are based. But, as fair comment, one may say that if, with the technic employed, this immunity phenomenon to pneumococci has not been observed, then the remaining experimental work, with its tepid conclusions as to the activity of sulfapyridine, may perhaps also be explained by differences in technic.

I submit that my own experimental results, which show that sulfapyridine is vastly superior to sulfanilamide in the treatment of experimental pneumococcic infections, which results have been completely confirmed by Fleming's in vitro work (*Lancet* **2**:74 [July 9], 564 [Sept. 3] 1938), and that the word "vastly" is a much more accurate description than that given by Dr. Long, who admits merely that sulfapyridine is "somewhat superior." Were Dr. Long's estimate correct, then during the three years that sulfanilamide has been widely used there should surely have been more than a mere handful of successes (usually type III) claimed for sulfanilamide in pneumococcic infections. As it is, during the mere nine months in which sulfapyridine has been available in limited amounts there have been clearcut reports concerning its effectiveness in the clinical field, and these have been made by competent observers in England, Africa and America; the two articles in your issue of February 11 are admirable examples.

The letter of Drs. Bullowa, Plummer and Finland (p. 570) opens with a ponderous warning concerning the futility of "many agents, chemical, physical and biologic, that have been recommended for the treatment of pneumonia." So far as I am aware, few if any of the "recommendations" quoted in the list have been based on extensive experimental work giving consistent results; such remedies cannot, therefore, justifiably be bracketed with sulfapyridine. The same letter contains a special plea for the continued use of serum therapy. In relation to this point, a paragraph in the original article of Drs. Flippin, Lockwood, Pepper and Schwartz (p. 531) contains the following significant statements: "Several patients who had received large doses of serum without apparent effect were given sulfapyridine and recovered," and "We instituted treatment . . . regardless of complications or the apparent terminal condition." The successes claimed for serum would be greatly altered by this test, for it is well known that a critical result with serum can be expected only when the patient is treated in a satisfactory stage of the disease.

The United States of America can provide a large amount of material for assessment under controlled conditions. It is earnestly to be hoped that further trials with sulfapyridine will produce the consistent clinical results that have already been reported from America.

LIONEL E. H. WHITBY, M.D. (CAMB.), F.R.C.P. (LOND.)
Bland-Sutton Institute of Pathology,
Middlesex Hospital, London, W. 1.

To the Editor:—I am sorry that Dr. Whitby has taken exception to parts of the report which I made to the Council on Pharmacy and Chemistry concerning the experimental and clinical status of sulfapyridine (THE JOURNAL, February 11, p. 538). I have no desire to enter into a controversy with him over our respective views on the experimental effects of sulfapyridine, as such a course wastes time and effort and rarely serves a useful purpose. However, since Dr. Whitby feels that he has been misquoted, both as to the content of his work and as to the interpretations which he has derived from certain of his investigations, courtesy requires an answer.

A rereading of Dr. Whitby's Bradshaw lecture (*Lancet* **2**:1095 [Nov. 12] **1938**) still leads me to the belief that "experimental detail" is lacking in his report concerning the therapeutic efficiency of the drug in staphylococcic infections in mice. It is well known that mice are quite resistant to experimentally produced staphylococcic infections, and while protocols of the results of experiments are given in this paper there is no mention of the origin of the strain of staphylococcus or the route or method of inoculation employed. Without this information a repetition of his experiments would be impossible.

Dr. Whitby's second point has some justification in that, although he wrote "the organisms showed degenerative capsular changes," he did not state that "the drug acts by bringing about degenerative changes in the capsular material" but said: "It [the drug] appears to exert a definite action upon the pneumococcus capsule" (*Lancet* **1**:1210 [May 28] 1938). Apparently I interpreted his remarks too literally on this point.

As I mentioned before, I have not been able to confirm Dr. Whitby's observation regarding the development of immunity in mice infected with pneumococci and treated with sulfapyridine. In the limited space allowed me for my special article I did not go into any explanation for this but, as he surmises, it can be attributed to differences in technic—or rather in the strains of pneumococci employed in the two laboratories. The strains used in my laboratory are not only highly virulent but are also rapidly invasive. With our type I strain the inoculation of one or two organisms causes the death of a mouse within twenty-four hours. Dr. Whitby's strain seems almost as virulent, in that his inoculation of five organisms generally killed control mice, but the average survival time of such animals was 3.3 days. This longer survival time evidently permits Dr. Whitby to use much larger inoculums and still get survivals in mice treated with large doses of sulfapyridine. These surviving

mice, having received a larger dose of antigen (pneumococci) than ours, may well be immune to homologous reinfection. The smaller inoculums of pneumococci used to infect our mice do not produce immunity in the surviving animals.

In our experience with the highly virulent and rapidly invasive strains, it has been difficult to obtain an appreciable number of surviving mice even though treatment was begun immediately after the infection and was continued intensively over a period of seven days. Out of 115 mice infected with about a thousand type I pneumococci each and treated with sulfapyridine, only seven survived, and while the life of mice infected with types II and III pneumococci and treated with the drug was prolonged, none survived. Hence in our hands sulfapyridine has been "somewhat superior" to sulfanilamide in the treatment of pneumococcic infections in mice and not "vastly" superior.

PERRIN H. LONG, M.D.,
The Johns Hopkins Hospital,
Baltimore.

FUNGOUS INFECTIONS TREATED BY IONTOPHORESIS OF COPPER

To the Editor:—The article "Fungous Infections of the Hands and Feet Treated by Iontophoresis of Copper" by Haggard, Strauss and Greenberg, in the April 1 issue of THE JOURNAL interests me. May I comment regarding the evidence on which their report is based? The authors neglect to prove that the cases they cite are of fungous origin and, by inference, must consider an exact mycologic diagnosis of their cases to be unimportant. Assuming that an accurate clinical diagnosis of dermatophytosis was possible in every instance, the reader is still left in doubt as to the species of fungus responsible. A report on the treatment of pneumonia in which the signs of rapid breathing, fast pulse and fever were the only reported diagnostic signs would probably be considered somewhat archaic. It is known that there is a wide variation in the therapeutic response to medication of the superficial fungous diseases according to the species of infecting micro-organism. Many cases of acute eczematoid eruptions of the hands and feet (fungous and nonfungous) respond to conservative measures, such as intermittent baths of potassium permanganate (1:3,000), superficial roentgen therapy in fractional doses and the application of bland dusting powders. When treatment of such cases is given in this way the time for apparent cure will be found to compare favorably with the average time of more than five weeks required by the authors in their reported series. Acute dermatophytosis is often overtreated, and keratolytics or fungicides used in strong concentration may produce secondary eczematization. The authors admit that their study has not been adequately controlled. Is it not trite to inquire why they should desire to publish their observations when they are incomplete? Even a preliminary report in which they say they have demonstrated that iontophoretic administration of copper causes response in dermatophytosis of the hands and feet should contain laboratory proof of the existence of an infection, cultural determination of the species of pathogenic fungus, evidence that other treatment —such as wet soaks of potassium permanganate—would not do as well, and negative laboratory results when the patient is considered cured. The degree of positive reaction, or the presence of a negative reaction to trichophytin, would also be of value and interest. Had the selection of cases included infections due to Trichophyton purpureum (in which there is no likelihood of spontaneous cure), the evaluation of the specific fungicidal effect of iontophoresis of copper might have been more fairly determined. The method may be valuable, but a report such as this does not leave this reader unduly impressed with its specific fungicidal effect. Pathogenic fungi are rarely found on normal skin. This is borne out by the work of Downing, Nye and Cousins (whose article the authors quote but could hardly have read carefully) and of other investigators. There are numerous saprophytes on normal skin, but these have no place in a discussion on dermatophytosis.

GEORGE M. LEWIS, M.D., New York.

"TRICHINOSIS"

To the Editor:—The editorial on trichinosis (THE JOURNAL, March 18, page 1074) by supplementing other efforts to emphasize the prevalence of trichinous infestations, will do good, making the profession more keenly aware of the possibility of this diagnosis. Since it may be interpreted as exaggerating the situation, it may do harm by delaying the control of the condition by rational methods. The industries concerned in hog raising and the marketing of pork products are now being approached by means of conferences to adopt some voluntary program of control.

The editorial fails to discriminate between minor degrees of infestation, which are to be shown post mortem only by refined technics, and the clinical entity trichinosis. The demonstrated high incidence of trichinous invasion does argue a potential menace of large proportions, but the small number of reported cases of trichinosis furnishes an argument for those who wish to believe that most of these invasions are of little importance. The estimate in the article of "48,000,000 cases of trichinosis" may readily be interpreted by those so minded as a reductio ad absurdum of the argument for the existence of a serious menace. The validity of applying maximum figures to the entire country also may well be questioned.

As a minor point, which nevertheless does have a bearing on the significance of the maximum figures of Evans, the misstatement regarding technics may be cited. The press preparation method is in reality the "old method," in use for some fifty years, while the digestion-Baermann technic is relatively recent. Again, Evans's use of the combined technics is no innovation, since the determinations at the National Institute of Health were made by the combined methods. Evans's higher figures, unless indeed they are due to the examination of a greater number of skeletal muscles per case or to the error incident to a relatively small sample, would appear therefore to reflect merely a higher local incidence, from which the derivation of country-wide figures would not be justified.

Believing as I do that many clinical cases of trichinosis fail of recognition, I regard the editorial as a step in the right direction of increasing professional awareness.

L. R. THOMPSON, M.D., Washington, D. C.
Director, National Institute of Health.

"PHYSIOLOGY OF THE BRAIN STEM"

To the Editor:—In the issue of January 21, page 267, of THE JOURNAL I see that the review of my monograph "Beiträge zur Physiologie des Hirnstammes" (contribution to physiology of the brain stem) contains a serious error. This review ascribes to me the opinion that the dampened and interrupted direct current selectively stimulates the fibers and centers of the autonomic system. Actually, I have demonstrated, and have also so described it, that by the interrupted (pulsating) direct current with dampened potential fluctuations the stimulus thresholds of the animal and of the autonomic systems are brought nearer to each other. The incorrect statement in the review is misleading to the neurophysiologist and neurologist, and an entirely impossible point of view is ascribed to me.

PROF. DR. W. R. HESS,
Rämistrasse 69,
Zurich, Switzerland.
Director, Physiologisches Institut
der Universität Zürich.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PHYSICAL FITNESS INDEX TESTS

To the Editor:—What is considered the validity of the physical fitness index tests? In a review of recent strength-testing literature, Frederick Rand Rogers, Ph.D., made the following statement: "That physical educators will be called on more and more to increase pupils' health is revealed by each new report of conditions in the medical field. The plain fact is that physicians, nurses, public health services and hospital organizations are not now keeping abreast of the nation's health problems. Even if they were, they still would only serve 2 to 3 per cent of the population, chiefly preventing these from losing their lives before reaching nature's appointed span. Who is to care for the 30 or 40 per cent whose health is regularly below normal, and steadily slipping down the scale, if not physical educators? And what is health? . . . This is abundantly muscular power and coordination, which are measured most objectively, reliably, economically and interestingly to subjects by the simplest forms of strength tests." Is this a view which physical educators generally will accept and put into practice? A notice in the *Bulletin* of the Indiana State Board of Health for October 1938 was as follows: "Frederick Rand Rogers, director of physical education at Boston University, has written us as follows: 'This is to report that a Boston manufacturing concern, the DuWard Company of 51 Cornhill, Boston, is now experimenting with new designs for physical fitness testing instruments far superior to those now on the market, which they claim they can sell at greatly reduced prices. For example, the new back and leg dynamometer at less than $100 (the present instrument is listed at $200 and sold at $160-$180). As you know, the chief stumbling block to the use of P. F. I. tests has been the exorbitant cost of dynamometers; therefore we are overjoyed at this new development. This note is a warning; if you know of any one about to order dynamometers, have them wait for the new instruments, or at least until we have a chance to examine and recommend or disapprove them.'" What do you think of this? Finally, I should like to ask what steps the family physician should take when the tests show a low status.

M.D., New York.

ANSWER.—[This question has been referred to workers in the field qualified to express opinions on the subject. The answer is based on their combined views.]

This question revolves around the validity of interpreting the degree of muscular strength as a definite reflection of physical fitness. Certainly even though a patient shows high muscular ability in a test it does not follow that his entire physical condition is definitely established. The human body is too complicated to attempt a diagnosis of physical condition by muscular strength alone; furthermore, it is quite generally conceded by students of the subject of physical fitness that performance tests are not as useful and as discriminating in the estimation of physical condition as the nonperformance tests. All strength tests are performance tests and hence require the conscientious cooperation of the examinee. In connection with the statement made by Rogers that "'the capacity of an individual for work is a useful measure of his health'" it may well be asked "What kind of work?" Most individuals today are not called on for great efforts of muscular power. Physical fitness after all is the ability to adjust to the environment and is related quite as much to the countless chemical and physical processes continually taking place as to the ability of muscles to do work.

The physical fitness index test, or the Rogers test, came into use during the early years of the present vogue for what is called "tests and measurements in physical education." In fact, so widely has this test spread in elementary and in secondary schools that it is being put to the following uses in Brookline, Mass.: (1) as the basis for the physical education activities program prescribed individually for every pupil, (2) as a guide to the evaluation of teaching procedures, (3) as a yardstick against which to consider academic load (the physical fitness index purports to determine not only a child's capacity for physical activity but "to a significant degree also his capacity for mental endurance"), (4) as a criterion by which the nutritional status and health habits may be judged, and (5) apparently as a check on the adequacy of the medical examination. The school physician is without laboratory facilities, including x-ray examinations, blood tests and determinations of the basal metabolism. The physician presumably therefore misses certain important conditions affecting physical fitness. The impression one gathers is that the physical fitness index is a tool of superior diagnostic value. Armed with this tool the physical educator, "cognizant of all defects," is now being a guide to the doctor, the school nurse, the classroom teacher and the parent (Hines, Thomas H.: A New Emphasis on Health, *J. Health & Physical Education* **10**:20 [Jan.] 1939). On a priori reasoning alone, the physical education profession must be considered bold indeed to presume serious diagnostic significance inherent in a test administered at the rate of "about a minute per pupil for corps of testers." No physiologist would be willing to say that physical fitness can be judged primarily on the basis of strength, when strength is measured by a battery of tests involving single, maximal efforts. Dynamometer tests are notoriously subject to profound variations from psychic causes alone. Strength probably fluctuates moderately as all biologic functions do. What its normal limits of variation are for the Rogers strength test has never been satisfactorily studied. No valid test of physical fitness can disregard the inclusion of a direct or indirect estimate of the response of the cardiovascular respiratory system to measured work. If instead of dynamometer tests the Rogers battery measured the "staying power" of the major big muscle groups, the load, speed, duration and rate of doing work being controlled, its score would have vastly more value. A battery of tests composed of single maximal pulls on a dynamometer certainly does not indicate a child's "capacity for sustained physical activity or endurance."

The following general criticism of the whole test and measurement program prevents taking its results seriously: 1. The instruments used are meticulously calibrated. 2. The technic of the administration of the tests is carefully taught and the reliability of each operator is particularly measured. 3. The subject, however, is handled as a robot, unaffected by meals, fatigue or psychic disturbances. There is no regard for the fundamental rule that in all human research one should begin with a subject in an essentially "basal" condition and then carefully control the environment in which the tests are administered. 4. The data are subjected to involved statistical analyses and the numbers derived uncritically accepted whether there is sense behind the variables being related or not. Statistical methodology has taken the place of reason. 5. There is yet to be seen any evaluation of physical education fitness tests in a physiologic sense or any discussion of the possible mechanism whereby defects (the wen with the cancer beneath it) may be logically thought to modify physical fitness.

It may be safely concluded that current scientific opinion cannot grant that physical fitness can be deduced from one set of measurements alone or that muscular strength is either an accurate or a valuable index of physical fitness. (If it were, why is it that women at practically all ages have a longer life expectancy than men?) The skeletal muscle might be in good shape while there was difficulty impending in the smooth muscle of the viscera. Of all measurements, those of muscle might be considered the poorest. Emotional states determine their energy output in a large measure, and this is a serious objection. Positive performance tests are notoriously hard to control. Devotion to one test and the advice that all others be discarded for experimental purposes when associated with advertisements for $100 dynamometers do not lend credence to the scientific nature of the studies reported.

SPHENOPALATINE NEURALGIA AND STELLATE GANGLION

To the Editors:—What information can you give me about the stellate ganglion especially in relation to sphenopalatine neuralgia?

A. L. LANGHORST, M.D., Elgin, Ill.

ANSWER.—Sphenopalatine neuralgia was first observed clinically by Sluder in 1920. He stated that the sphenopalatine ganglion could include some cells which were sensory or afferent in function. The ganglion itself, located deep in the sphenopalatine fossa, was known to receive both preganglionic and sympathetic fibers, the preganglionic or motor fibers being components of the facial nerve, while the sympathetic fibers were derived from the plexus of the internal carotid artery. It was felt by Sluder that infection from the sinuses might invade the sphenopalatine ganglion and give rise to neuralgia. Recent anatomic studies, however, do not support the opinion that the sphenopalatine ganglion contains afferent ganglion cells or pain fibers.

The stellate ganglion, however, is formed by a fusion of the first and sometimes the second thoracic ganglion with the inferior cervical ganglion of the sympathetic trunk. This is such a long distance away anatomically from the sphenopalatine ganglion that the connections between the two, if there are any, must cover a devious pathway. There is no evidence that they have any clinical connection, although the question presented may have arisen from the fact that alcohol injection or removal of the stellate ganglion has occasionally been performed in an attempt to relieve pain in the face. It rarely occurs that facial neuralgia of unusual type persists after cutting the posterior root of the fifth cervical nerve, thus presumably denervating the

entire side of the face. It is for this type of neuralgia that the stellate ganglion has been removed in the past, in the hope that through vasomotor or secretory changes the persistent neuralgia will be relieved. The operation has not, in general, proved successful, although a few cases have been reported in which relief was obtained. It seems unlikely that this operation has been performed for relief of Sluder's neuralgia, for the neuralgia Sluder originally described is now not accepted clinically. It should be pointed out, nevertheless, that there still are certain obscure types of facial neuralgia the cause of which is not known.

PSEUDOBULBAR PALSY

To the Editor:—A woman aged 62, following a prolonged upper respiratory infection last spring, developed a hypertensive encephalopathy during the summer. This cleared up and aside from general weakness she was as well as could be expected until two months ago, when she suddenly noticed some difficulty in speech, and examination revealed a palsy of the lower part of the left side of the face. There was also dysphagia. The speech difficulty improved quickly and also the facial palsy, but in about two weeks or so it was noticed that there was a weakness on the right side of the face, the dysphagia persisting. However, after about another six weeks there was definite improvement in the dysphagia, and the right side of the face was practically normal, when suddenly she again developed some difficulty in speech and there was again a weakness of the left side of the lower part of the face. The systolic tension varies between 180 and 220 and the diastolic between 100 and 110. Eyeground examination shows evidence of arteriosclerosis, and there are some old small hemorrhages. During the siege of the hypertensive encephalopathy she had marked pain in the lower part of the back and lower extremities and the latter were tender. About two months ago when the first attack of facial palsy was noted she complained of a good deal of pain and tenderness in the right gluteal region. I might also add that when the right facial palsy was noted she complained somewhat later (about two weeks) of weakness in the right hand and upper extremity. This has improved. She also cannot retain urine as well as previously. She wears an upper and lower denture. How would you explain this varying picture, and what would you do?

M.D., New York.

ANSWER.—The observations submitted suggest a syndrome of pseudobulbar palsy. This is usually due to bilateral small hemorrhages or thrombi in either hemisphere of the brain secondary to cerebral arteriosclerosis and hypertension. These lesions involve both the right and left pyramidal tracts in the brain, producing bulbar symptoms by loss of voluntary innervation and not by actual paralysis. Any good textbook in neurology should be consulted for a detailed description of the clinical symptoms. The prognosis is usually unfavorable. The condition may last for years and the symptoms may even disappear for a time. The treatment is entirely symptomatic, depending on the underlying condition (arteriosclerosis and hypertension). Because swallowing is difficult, care in feeding is generally necessary.

HYPERTENSION AND MENOPAUSE

To the Editor:—A woman aged 45, in the menopause, has a hypertension varying from 160 to 200 systolic. All other causes of hypertension have been eliminated; there are no foci of infection, nephritis or arteriosclerosis. In similar cases I have used theelin in oil with excellent results. I tried to use it in this case but her symptoms were aggravated: dizziness, nervousness and pressure. What type of treatment would be indicated?

M.D., Missouri.

ANSWER.—The information given is so meager that it is almost impossible to discuss the therapy adequately. Each instance of hypertensive arterial disease presents a new and different therapeutic problem. It is vitally important to know, for example, the level of the diastolic tension and whether or not it is fixed or variable. One is doubtful also as regards the proof that "there is no nephritis," for the mere absence of proteinuria is often erroneously taken as a criterion of normal kidneys. Thorough study of the renal function is necessary before one can say with certainty that renal functional impairment does not exist. The relative youth of the patient and the variability of the systolic tension suggest an endocrine factor in the etiology of this instance of hypertensive arterial disease but by no means prove it; additional data might well demonstrate an aortic regurgitation as a cause of the systolic hypertension.

Before advising the institution of any therapy, one must urge that additional diagnostic information be acquired. Sources of psychic turmoil must be carefully sought for and judiciously analyzed; anxiety, fear, discouragement and the like are significant factors and, if present, the prolonged use of mild sedation (such as with sodium bromide 0.6 Gm., or 10 grains, thrice daily) is indicated. Of first importance is a determination of the basal metabolic rate; thyroid disturbances are very common at the age of this patient and are often misleadingly masked. In such instances the major rise is in the systolic tension. As mentioned, renal function studies are also desirable and careful blood studies, for anemia is a not uncommon, although most frequently ignored, provoking etiologic factor in hypertension. Should the basal metabolic rate be elevated and/or anemia exist, the therapeutic indications become clear: the correction of these abnormalities. Should these tests yield evidence of normal conditions, endocrine therapy is worthy of trial. The gonadotropic extract from pregnancy urine, antophysin (Winthrop), follutein (Squibb), A. P. L. (Ayerst) or antuitrin-S (Parke, Davis) may be of value. Of greater importance, however, is the general dietary and hygienic management, which must include an adequately liberal fluid intake, a balanced diet and avoidance of excesses of condiments and spices. Proteins should not be radically restricted, for the problem is not to treat the disease but to treat the patient who has the disease, and prolonged restriction of protein intake depletes the body's resistance to infection and aggravates any tendency to anemia. Sufficient rest, calm reassurance and wise understanding and advice regarding the petty annoyances of existence can do much toward combating the psychic turbulence so characteristic of the "stormy menopause." Mild vascular sedatives of fairly prolonged action, such as sodium nitrite, erythroltetranitrate and bismuth subnitrate are worthy of trial. Sodium thiocyanate is too toxic to be used unless the patient is under exceptionally close control and frequent observations of the blood thiocyanate level are made.

THE "RADIONICS" HOAX

To the Editor:—Has there been any scientific research to determine the usefulness of Radionics in the diagnosis and treatment of disease?

M.D., California.

ANSWER.—"Radionics" is an outgrowth of the infamous Abrams quackery devices known as the "Oscilloclast," the "Electro-Concusser," the "Biodynamometer" and the "Sphygmobiometer." There is no evidence to indicate that any scientific investigation has ever been made of these devices. Indeed, there would seem to be no reason for making such a study. It is interesting to note that the editor of the *California State Journal of Medicine* and a member of the publication committee of the Medical Society of the State of California proposed a test of the Abrams device to Dr. Abrams. He refused flatfootedly in any way to cooperate in such an investigation (THE JOURNAL, June 10, 1922).

In some of the advertising for "Radionics," it is stated to be "the science of detecting and locating diseases by a mechanical action on magnetic waves produced by the radiation of ions through an instrument especially constructed for direct application to the human body" ["Alice in Wonderland" makes amusing reading too.—ED.]—"it being no more possible to find ulcers of the stomach if ulcers are not present than it is to get a Chicago station by turning a dial on your radio to a Detroit station." The latter is not so difficult as implied, if reference is to WJR in Detroit and WGN in Chicago.

Other advertising includes the statement that since "a famous American diagnostician has declared that over 50 per cent of diagnoses are wrong . . . 50 per cent of the 'doctoring' public are being 'doctored' for the wrong thing." Just in case this isn't fallacious enough to serve as an irrational basis for adopting this illegitimate offspring of an illegitimate offspring of medicine, it is added that "the chiropractor has been greatly aided in his analysis of a patient's condition by his ability to locate nerves, which because of interference have been unable to function normally; but even this additional advantage [provided it were true.—ED.] has left still much to be desired [more especially a modicum of medical science.—ED.] in obtaining positive and definite information free from the fear of contradiction."

Such problems, however, are "simple" in the eyes of the totally uninformed radionic enthusiasts, for, believe it or not, it is claimed that radionic examination will not only determine the presence of but will actually measure the intensity of "general poison, bacterial poison, inflammation, tissue degeneration, cancerous tendencies, pus and poison producing bacteria, tuberculosis, acidosis, diabetes, fibrous tissue [sic—ED.], cysts, ulcers, etc." and will indicate in which organs the conditions found are primary and in which secondary.

Continuing more of the buncombe found in the advertising for radionics: "Countless examinations have proved beyond a peradventure that the catarrhal and mucous discharges from the orifices of the body (nose, throat, ears, etc.) are frequently only secondary conditions, being the channels used by the body for the elimination of poisons arising elsewhere. For instance, a case of discharge of mucus and pus from the nose, having been under various forms of treatment for four years, was found to be due to an inflamed and infected condition of the liver ["the

newer pathology"—ED.] the source of poison in a much-treated case of 'rheumatism' was found to be in the large intestine, which, when properly cared for, resulted in a total disappearance of the rheumatic symptoms. In a case diagnosed as 'female trouble' and 'appendicitis' the gall bladder was found to be infected and inflamed. When the spinal cause of this ["chiropractic pathology"?—ED.] had been corrected the so-called appendicitis and other troubles vanished."

Finally, it is stated that "Radionics is not a substitute for Chiropractic, but a material aid to the Chiropractor inasmuch as it is in complete harmony with Chiropractic principles. Radionics operates totally in accord with science ["ignorance of" would be more accurate than "accord with."—ED.], and offers absolute scientific proof of the truth and sanity of the Chiropractic Philosophy [comparable to proving astrology by numerology.—ED.] that nerve interference is a primary cause of disease."

It is noted that all of these statements are made without any references to scientific texts or any reports in the medical or other literature, or to anything. There is no reason to institute any scientific research to determine the usefulness of radionics, when it does not even pretend to be based on anything even faintly resembling scientific evidence or, more accurately, on any evidence. It is so palpably over the borderline of science and scientific medicine and in the field of pseudomedicine and quackery that it does not deserve to be glorified by being given any consideration by scientific workers.

ANTIRABIC TREATMENT

To the Editor:—Dec. 17, 1937, a man and his wife called and gave the following history: They had been bitten on the forearms by their pet dog the previous day. The dog was observed by a veterinarian until December 18, when it died. The head was examined in the laboratory; Negri bodies were present. I gave both patients twenty-one injections of antirabies serum, two a day for the first week and one a day for the second. Neither has developed symptoms of rabies. Two weeks ago the woman was scratched on the forearm by her house cat. The cat later developed diarrhea and paralysis of the hind quarters and died on February 21. The head was examined in a laboratory within two hours after death. No Negri bodies were found. Both the husband and the couple's two sons had played with the cat during this time. No marks or scratches were found on the father's or sons' bodies. Should the four members of the family receive antirabies serum? If so, should the frequency of the dosage be the same as in the previous course of treatment? Should the children receive only prophylactic treatment? If so, how many injections should be given and how frequently? The pathologist at the laboratory has inoculated a rat with the serum from the brain of the cat. If the rat should develop no symptoms of rabies or the postmortem examination show no Negri bodies, should treatment be discontinued?

M.D., Illinois.

ANSWER.—There does not seem to be any compelling reason why the woman, the husband or the two sons should be given antirabic treatment.

POSSIBLE NEPHROSIS FROM PAINTS

To the Editor:—Have you any information on the effects of paint on the kidneys? A girl with definite nephrosis has been for a number of years a painter in a furniture factory, using both lacquers and turpentines and oil paints, always with a brush and never with a spray.

S. J. WOLFERMANN, M.D., Fort Smith, Ark.

ANSWER.—The kidneys may be involved as one aspect of many types of occupational diseases, including those which may follow exposure to turpentine, benzene, divers alcohols and other possible constituents of paint. However, the occurrence of nephrosis as the single manifestation of injury from some industrial intoxicant is unusual. In benzene poisoning nephritis may appear, but commonly this is overshadowed by other evidences of benzene injury such as anemia, leukopenia, hemorrhagic states or lowered resistance to infection. Any claim as to the occurrence of nephritis after exposure to benzene as the single and exclusive manifestation of benzene insult is open to question. The renal system may be involved in a general picture of damage through industrial agents, but rare indeed is this one system specifically damaged to the exclusion of others. Alice Hamilton, in "Industrial Poisons in the United States," quotes from the report of the British Commission on Industrial Paints as follows: "There is not sufficient ground to warrant us in accepting the view that turpentine poisoning is the cause of the leading symptoms commonly attributed to either acute or chronic lead poisoning, nor in attributing to the inhalation of fumes of turpentine and other thinners the occurrence of chronic Bright's disease." Dr. Hamilton herself does not fully accept this quoted statement and in turn says "Turpentine vapor appears able to set up acute nephritis and repeated attacks might be expected to terminate in chronic nephritis, unless those exposed establish some sort of immunity to vapor. Of such immunity there is no clear evidence." The stand here taken is that the occurrence of nephrosis in a worker exposed to various substances entering into paint and lacquers does not in itself constitute proof that the work materials are responsible.

BISMUTH HYDRATE COMPOUND NOT CAUSE OF DEATH

To the Editor:—Recently I was called to attend an infant of 6 months who died in less than twenty-four hours after having taken three doses of bismuth hydrate compound as per the accompanying formula. The dose was one teaspoonful every two hours, the symptoms beginning within about forty minutes after the last dose. In the absence of any other reasonable cause of death I would be glad to have your opinion on this case with information as to other similar cases if any have been reported. As you are aware, this dose was relatively large, being about six times the amount specified by the company that puts out this compound, but at the same time it is generally understood that none of the ingredients are considered highly toxic. Nevertheless the symptoms from the onset until death, which occurred about twenty hours after the family noticed evidence of a collapse, the onset of which was rather sudden, included cyanosis, depressed respiration and staring eyes with dilated pupils, although the baby did not seem to be completely unconscious at the beginning. At first there was no fever, the temperature being 96 F., but within a few hours the temperature began to rise and reached 102 about fourteen hours after the onset of symptoms. At the end of approximately fifteen hours the temperature began to decline as death approached. Also at the beginning there was considerable rattling in the chest, seemingly from mucus, but under the administration of respiratory and cardiac stimulants the noise in the chest disappeared but returned later as death became apparent. There was from time to time slight vomiting, something like once each two to three hours, not excessive at any time.

HENRY B. MAY, M.D., Benavides, Texas.

Bismuth Hydrate Compound

Formula: Each fluidounce represents:	
Chloroform	2 minims (0.12 cc.)
Bismuth oxycarbonate	10 grains (0.643 Gm.)
Fluid red gum (kino eucalypti)	32 minims (2.16 cc.)
Pepsin	4 grains (0.259 Gm.)
Phenyl Salicylate	1 grain (0.064 Gm.)
Alcohol	2 per cent
Oil and aromatics	q. s.

Action and Uses: Astringent and carminative, for use in the treatment of gastrointestinal irritation and fermentation and in diarrheas of various origins.

Supply: Bismuth Hydrate Compound—Bottles 4 ounces, 16 ounces, and 1 gallon.

Administration: From one to two teaspoonfuls every half hour for six or eight doses; children 10 drops to half a teaspoonful.

ANSWER.—The amounts of each of the ingredients of the prescription which the infant received in the three teaspoonfuls given are approximately as follows: chloroform 0.05 cc., bismuth subcarbonate 0.25 Gm., fluid of red gum (kino eucalypti) 0.81 cc., pepsin 0.09 Gm., phenyl salicylate 0.024 Gm., alcohol 0.22 cc. The nature of the oil and aromatics is not stated but it is presumed that they are nontoxic in the amounts used.

Although the dose given the 6 months old infant was about six times the recommended dose, the amounts of the various ingredients were small. The small amounts of the bismuth subcarbonate and the pepsin would certainly rule them out as the cause of death. The dose of kino eucalypti is from 5 to 20 grains (0.3 to 1.2 Gm.) of the solid gum. In this case only 0.81 cc. of the solution was used. The acutely fatal dose for chloroform when swallowed is not known with certainty, but 1 ounce would be dangerous (*Sollmann*). The infant received slightly less than 1 minim. Phenyl salicylate under ordinary conditions passes through the stomach unchanged, being hydrolyzed in the intestine into its components, phenol 40 per cent and salicylic acid 60 per cent. However, human milk may split it into its components (Usener) and hence in nursing infants it might give rise to a gastritis if given in large enough amounts. In this case only 0.024 Gm. was given, which would give approximately 0.009 Gm. of phenol and 0.014 Gm. of salicylic acid. These quantities are too small to give rise to dangerous symptoms, much less cause death. The 4 minims of alcohol is negligible as a cause of death. In addition these drugs were not given at one dose but were distributed over a four hour interval of time. As far as can be learned there have been no similar cases reported from this mixture.

The fact that the onset of symptoms began after the administration of the prescription might point to it as a factor in the production of symptoms, but in this case, having the possibility of violent specific allergic reaction to one or more of the ingredients, it may be presumed that the mixture was not the cause of death.

RADIUM POISONING FROM WATCH DIAL PAINTING

To the Editor:—I am interested in learning the incidence of radium poisoning in watch dial painting. A woman, aged 33, married, has necrosis of the mandible and superior maxillae. The Wassermann reaction and physical examination are negative. The patient worked at dial painting until twelve years ago, when she states that she was declared to be entirely negative so far as radium poisoning was concerned.

BERNARD R. BERKOWITZ, M.D., New York.

ANSWER.—Bony destruction of the mandible and upper maxillary in a woman previously employed in dial painting work using radioactive substances at once suggests an effect and cause relationship. The presence of radioactive substances in the body may be precisely determined even at this late time since the active period of the radioactive substances ordinarily employed far exceeds twelve years. Suitable x-ray, electroscopic or Geiger counter examination is required. The procedures involved are described in the *Journal of Industrial Hygiene* **20**:36 (Jan.) 1938 in an article entitled "Hazards in the Radium and Mesothorium Refining Plant at the University of Missouri." This article contains the following quoted statement:

> When radium or mesothorium is carried in the blood stream or deposited in the body it is possible to detect its presence by measuring the alpha ray activity of the expired air.
>
> The alpha ray measurements of radon in the expired air were made by having the worker blow through a drying tower and then through the ionization chamber of a calibrated electroscope until the air within the chamber had been replaced by the air from the lungs.

In New York, workers at the Columbia University College of Physicians and Surgeons are believed to be experienced in problems of this character and equipped with adequate apparatus for the performance of necessary testing. If the commoner causes of bony necrosis about the mouth can be ruled out, it becomes highly probable that precise proof can be adduced that the present condition is due to the action of radioactive substances connected with work twelve years or more ago.

POTASSIUM SALTS IN DIABETES MELLITUS

To the Editor:—I understand that some work has been done on the potassium alterations in diabetes mellitus. Can you enlighten me on this subject, mentioning references?

M.D., New York.

ANSWER.—Rathery and Bertoliatti (*Compt. rend. Soc. de biol.* **117**:875 [Dec. 1] 1934) reported that in patients with uncomplicated diabetes the potassium content of the plasma was usually normal. In some cases in which the condition was advanced the value was increased. A detailed study of the electrolyte balance in diabetic acidosis is given in the paper by Atchley and his co-workers (*J. Clin. Investigation* **12**:297 [March] 1933).

Peters and Van Slyke (Quantitative Clinical Chemistry, Baltimore, Williams & Wilkins Company, 1935, vol. I, Interpretations, pp. 787, 1054) mention that whereas the edema of malnourished individuals with severe diabetes is aggravated by the giving of sodium chloride or sodium bicarbonate it may be relieved by potassium salts. For a further discussion the reader is referred to this textbook.

Kerr (*J. Biol. Chem.* **78**:35 [June] 1928) found that whereas the potassium content of the blood serum of depancreatized dogs was essentially the same as that of normal animals, following a dose of insulin large enough to produce well marked hypoglycemia there was a definite fall in the potassium level. Kerr states that the potassium content of the erythrocytes is, however, not affected by overdosage with insulin and concludes that the potassium which disappears from the serum after insulin does not enter the corpuscles.

McQuarrie, Thompson and Anderson (*J. Nutrition* **11**:77 [Jan.] 1936) in studies on diabetic children found that potassium chloride when given in doses of from 10 to 20 Gm. daily together with a simple diet low in sodium caused a slight fall in the blood pressure and a significant increase in glycosuria. These effects were exactly opposite to those which resulted from the administration of sodium chloride in large amounts while the patient was maintained on a diet low in potassium. A high intake of sodium chloride depressed the level of serum potassium. The observations mentioned are consistent with those of Silvette and Britton (*Proc. Soc. Exper. Biol. & Med.* **37**:252 [Oct.] 1937), who reported that the administration of subtoxic doses of potassium to rats led to glycogenolysis and hyperglycemia.

IODINE AND COMPOUND SOLUTION OF IODINE IN DISINFECTION OF THE SKIN

To the Editor:—1. If a bandage on a finger is completely saturated with tincture of iodine, will it endanger the life of the finger? Is necrosis likely to occur? If so, in what time? Note the following quotation from a clipping. If the statement made in it had been regarding a 5 per cent or even a 2 per cent solution of phenol it would be credible to me, but I doubt the statement regarding tincture of iodine: "The writer recalls a sad case of mistaken zeal with respect to antiseptics when he was a medical student. A maid working for a doctor's wife cut her finger. The wife, knowing medicine by marriage, bound up the finger and, taking no chances, soaked the dressing with tincture of iodine. When the bandage was removed, the finger was literally dead and had to be duly buried." 2. Is one part of compound solution of iodine in 63 parts of water an efficient disinfectant? See following quotation from a clipping: "To summarize: A good antiseptic for the medicine cabinet can be assured by getting an ounce or two of Lugol's solution (which had better have a poison label), and a four ounce bottle. Put a half teaspoonful of Lugol's solution into the empty bottle and fill it with tap water. This gives you an antiseptic which, according to approved tests, is as powerful as merthiolate, as cheap as milk, practically stainless and odorless, and so nontoxic that any amount a little child might drink from the bottle of the dilution would in all probability do no harm. What more do you want?"

M.D., Washington.

ANSWER.—1. To bind up a finger and then saturate the dressings with tincture of iodine is so extraordinary a procedure that little can be found reported in the literature to indicate what the result would be. Similar treatment does not cause necrosis of the foot of a small laboratory animal, however. On theoretical grounds it does not appear likely that a finger would, under such circumstances, suffer any more than intense staining, with subsequent loss of more or less skin, even though full strength iodine solution had been used. Tincture of iodine evaporates rapidly, leaving a deposit of dry iodine on the skin which penetrates the local tissues slowly and is absorbed by the body and excreted in the form of iodides (Nyiri, William, and Jannitti, Marie: About the Fate of Free Iodine upon Application to the Unbroken Animal Skin: An Experimental Study, *J. Pharmacol. & Exper. Therap.* **45**:85 [May] 1932). Moreover, as soon as iodine reaches the deeper layers of skin it becomes extremely painful, differing in this respect from the phenol group of disinfectants, which produce anesthesia as they advance. Hence, in the case described, it is not probable that the patient would have left the dressing in place if the iodine had penetrated far enough to damage the deeper structures of the finger.

2. A solution prepared in the manner described would contain approximately 0.083 per cent of iodine and 0.167 per cent of potassium iodide in water. Such a solution could not be expected to reduce, by any significant amount, the number of bacteria which are ordinarily present on the skin. If, however, even weak solutions of iodine are subjected to the commonly employed in vitro tests of germicidal power or to ordinary rubbing and scraping tests for disinfection of the skin, they may, unless carefully controlled by an effective neutralizing agent for iodine, give negative and therefore misleading results, owing to the inevitable carrying over of traces of the strongly bacteriostatic iodine into cultures. Despite the claims cited, therefore, this dilute preparation of compound solution of iodine cannot be considered an efficient skin disinfectant.

QUERIES AND MINOR NOTES

PARALYZED URINARY BLADDER AND CYSTITIS

To the Editor.—A woman aged 38 fell from a horse ten years ago, sustaining a fractured lumbar spine with resultant paralysis of some leg muscles and the urinary bladder. She has had good orthopedic care and can walk with the aid of a cane and a steel brace on the right leg. The problem is this. The bladder can be emptied only by pressure above the symphysis, which she herself manages. This means that there is a small amount of residual urine, which means a chronic cystitis. This has gone on for ten years. Since she moved to this community two years ago I have kept her quite comfortable and the bladder quite clean by a thorough weekly irrigation of the bladder at my office and an instillation of 5 per cent mild protein silver. She was recently in St. Louis on a visit and was taken to a physician (a urologist) for her weekly irrigation. After the treatment he advised her to take mandelic acid for a few days every week or so in order to keep her urine more nearly normal. I had talked this over with her at previous times but had advised her against taking any urinary antiseptic which would cause sufficient renal irritation to bring down red blood cells in the urine. I am perfectly willing for her to take mandelic acid if it is not liable to cause nephritis in time. I am not writing to ask who is right but what to do. The urine can be completely sterilized but in a short time will be back where we started because the bladder cannot be completely emptied each time. She is remarkably well and free from urinary distress if she has a weekly irrigation with boric acid solution. Is the amount of infection which must be present (pus cells are present in the catheterized specimen varying from a few to ten or twenty per high power field, but the urine is always clear) apt in time to do more damage to the organism than periodic dosage with mandelic acid with consequent periodic (though mild) renal irritation? Is mandelic acid too new for this question to be answered?

M.D., Michigan.

ANSWER.—The program carried out is a good one and should not be changed in any way. Mandelic acid, while not apt to cause nephritis, would probably not be recommended in this case. It might upset the stomach. The reason the infection in the urine recurs regularly after the urine has been sterilized is that the patient has residual urine.

It is possible that a presacral neurectomy is indicated in this case. It might be well to have a good neurologist examine the patient and discuss the possibility of this procedure. Finally, one might discuss the possibility of suprapubic cystostomy and establish a permanent drainage if presacral neurectomy is not indicated. Although this will prevent possible recurrence of bladder infection, it is a nuisance to walk around with permanent suprapubic drainage and should be done only as a last resort.

EPHEDRINE SULFATE FOR ENURESIS

To the Editor.—A girl, aged 8 years, has enuresis. Quite recently her mother told me of reading about a new treatment for this condition and she was under the impression that it was in Dr. Bundesen's column. Can you tell me whether there is such a treatment and where I can find it, if so?

JOHN R. PHILLIPS, M.D., Michigan City, Ind.

ANSWER.—The treatment referred to is the use of ephedrine sulfate. The method is described in the Sept. 11, 1937, issue of the *Lancet*. The treatment is based on the observation that, in the therapy of asthma with ephedrine, periods of anuria occurred. The amount of ephedrine is greater than that of the usual therapeutic dose. The experiments were carried out by Dr. R. W. Brookfield.

GLOBULIN DETERMINATION OF SPINAL FLUID

To the Editor.—What are the practical methods of globulin determination of the spinal fluid for office procedure? As the junior scopometer is no longer available, what other instruments may be used for globulin determination of the spinal fluid and where may they be obtained?

A. J. REICH, M.D., New York.

ANSWER.—Probably the simplest and most practical method of estimating the globulin of cerebrospinal fluid is that described by Matz and Novick (*J. Lab. & Clin. Med.* **15**:370 [Jan.] 1930) under the title "Improved Colorimetric Procedures for the Quantitative Estimation of the Proteins of the Cerebrospinal Fluid." This is a slight modification of procedures described by Wu (*J. Biol. Chem.* **51**:33 [March] 1922), Ling (*ibid.* **69**:397 [Aug.] 1926) and Wu and Ling (*Chinese J. Physiol.* **1**:161 [April] 1927). The method "Clinical Determination of the Albumin Globulin Ratio in Spinal Fluid" by Exton and Rose (THE JOURNAL, Jan. 3, 1931, p. 36), in which the junior scopometer is employed, could probably be used with other instruments for measuring turbidity. The Wu colorimetric procedure employed by Matz and Novick requires a centrifuge and a colorimeter, instruments which should be available in every clinical laboratory. Either a Klett biocolorimeter or a B. & L. biologic colorimeter is satisfactory.

Most American authorities (Merritt and Fremont-Smith: The Cerebrospinal Fluid, Philadelphia, W. B. Saunders Company, 1937, p. 33) seem to feel that the determination of the protein fractions in spinal fluid, in addition to the total protein, is of insufficient clinical value to justify the work involved. The simplest satisfactory method for total protein is the Denis method modified by Ayer, Dailey and Fremont-Smith (*Arch. Neurol. & Psychiat.* **26**:1038 [Nov.] 1931). Extensive studies in which the protein fractions have been determined, have been made (Kafka: Die Zerebrospinalflussigkeit, Leipzig and Vienna, 1930). The paper of Matz and Novick reports a large number of observations on albumin, globulin, total protein and the albumin-globulin ratio, chiefly in various forms of syphilis.

ACTION OF SNUFF ON NOSE

To the Editor:—If pulverized tobacco snuff is a mucous membrane irritant when drawn by inhalation into the nasal passages, how can it produce better breathing for having used it? Your help in solving what appears to be an incongruous situation, irritants producing congestion, better breathing, will be greatly appreciated.

M D, Louisiana.

ANSWER.—Snuff is a primary irritant and causes a burning feeling when first inhaled. Later on, as the habit is formed, the burning feeling is replaced by a sense of exhilaration. When the snuff is inhaled there results, as with the inhalation of all irritating materials, an excess flow of mucus and serum, which is followed immediately by sneezing and blowing of the nose, thus clearing the passages. This explains the fact that there is more breathing space after using such an irritant.

However, there are three dangers in the use of snuff. In long continued cases there is a tendency to atrophic rhinitis. In addition, polyps seem to occur rather frequently in users of snuff, and because of the excess of sneezing and blowing there is a distinct liability to infection of the sinuses.

ORGANIC DISEASE OR HYSTERIA FROM LIGHTNING

To the Editor.—A middle aged woman was sitting near a window in a shoe shop working on her machine when lightning struck, resulting in some fire damage to the building. When this occurred the patient had convulsive seizures, became unconscious and was taken to the hospital in an ambulance. This condition persisted for more than twenty four hours and when consciousness was regained the patient complained of severe headache particularly on the left side, pain and deafness of the left ear and loss of vision of the left eye. Also at the slightest noise she would begin to shake and tremble. Since this incident, which happened seven months ago, the patient has had a draining left ear, there is practically no sight in the left eye and she is still complaining of nervousness and headache. All the various laboratory tests, including Kahn, Kline and Hinton tests and urine and blood counts, have been negative. A spinal tap has been done. In your opinion is this a traumatic or fright neurosis superimposed by hysteria or is it possible that the lightning did strike her without leaving any sign of a burn? Is it possible for lightning to strike a person without leaving any sign of burns at the site of entrance? What is your opinion as to further treatment and as to prognosis? A competent ophthalmologist examined the eye and found the optic disk normal.

M D, Maine.

ANSWER.—It is rash to offer an opinion on such a case without examination. However, the account suggests fright-neurosis with conversion hysteria, rather than a condition resulting from a structural lesion.

For purposes of diagnosis of hysteria a normal appearing optic disk would be the condition of the pupils. Obliteration or serious reduction of light or convergence reflexes in the pupil would of course be strong evidence in favor of organic disease. It is most unlikely that complete blindness of an eye sustained by lightning of organic nature could exist with normal pupillary reflexes. If the diagnosis of hysterical blindness and deafness is correct the treatment is one of suggestion, i. e. succeeding in persuading the patient that blindness and deafness are not really existing. This is a matter of personal power on the part of the physician.

PROSTATIC STONES

To the Editor.—Please discuss the treatment for prostatic calculi in a man of 47. The stones have not caused symptoms. They are located too deep in the gland to be removed through endoscopy. One of the stones is about the size of a hazelnut and the others about two-thirds that size. Is removal by surgical intervention, that is, suprapubic cystotomy, advisable in the absence of symptoms?

M D, Arkansas.

ANSWER.—The general consensus among urologists is that the mere presence of stones in the prostate is no indication for their removal. If the stone or stones do produce symptoms, they may be removed. This may be accomplished by (1) removal of the stones by means of the resectoscope—removing the overlying prostatic tissue and washing the stones out of the prostatic bed, or milking them into the bladder and then evacuating them through the sheath of the resectoscope, (2) perineal prostatotomy or (3) suprapubic cystotomy.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, April 29, page 1754.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical nters having five or more candidates desiring to take the examination, ime 19 21 and Sept. 11-13. Ex. Sec., Mr Everett S Elwood, 225 S ith Street, Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY. An Affiliate of the American oard of Surgery. *Oral* examinations for all candidates, St Louis, May 1-14 *Written* Various places throughout the United States, Sept 9. pplications must be filed by July 11. *Oral* Part II Philadelphia, Oct 15 Sec, Dr Paul M Wood, 745 Fifth Ave, New York

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY Philadelphia, ct 30 Nov 1 Sec, Dr. C Guy Lane, 416 Marlboro St, Boston

AMERICAN BOARD OF INTERNAL MEDICINE *Written* Various sec- ons of the United States, Oct 16 and Feb. 19 Formal application must : received before Aug. 20 for the Oct examination and on or before in 1 for the Feb examination Sec, Dr. William S Middleton, 1301 niversity Ave, Madison, Wis

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY General oral, inical and pathological examinations for all candidates, Part II examina ons (Groups A and B) will be held in St Louis, May 15 16 Sec, Dr aul Titus, *1015 Highland Bldg, Pittsburgh (6)*

AMERICAN BOARD OF OPHTHALMOLOGY *Written* Various cities roughout the country, Aug 5. *Oral* St Louis, May 15 and Chicago, ct 7 Sec, Dr John Green, 6830 Waterman Ave, St Louis

AMERICAN BOARD OF ORTHOPAEDIC SURGERY St Louis, May ec, Dr Fremont A Chandler, 6 N Michigan Ave, Chicago

AMERICAN BOARD OF OTOLARYNGOLOGY St Louis, May 12 13 and hicago, Oct. 6-7 Sec, Dr. W P. Wherry, 1500 Medical Arts Bldg, maha

AMERICAN BOARD OF PEDIATRICS Cincinnati, Nov. 15. Appointments ust be made before July 15. Sec, Dr. C. A. Aldrich, 723 Elm St, innetka, Ill

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY Chicago, May 13. ec, Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, C

AMERICAN BOARD OF RADIOLOGY St Louis, May 11-14 Sec, Dr. arl R Kirklin, 102-110 Second Ave S W, Rochester, Minn.

AMERICAN BOARD OF SURGERY *Part II* New York, May 8 and lay 9 Sec, Dr J. Stewart Rodman, 225 S 15th St, Philadelphia

AMERICAN BOARD OF UROLOGY White Sulphur Springs, W Va, lay 26 28. Sec, Dr. Gilbert J. Thomas, 1009 Nicollet Ave, Minneapolis

District of Columbia January Report

Dr George C. Ruhland, secretary, Commission on Licensure, eports the written examination held in Washington, Jan 9-10, 939 The examination covered nine subjects and included sixty uestions An average of 75 per cent was required to pass Twelve candidates were examined, all of whom passed. Eleven hysicians were licensed by endorsement. The following schools ere represented:

School	PASSED	Year Grad	Per Cent
George Washington University School of Medicine (1936) 83 5, 85, (1937) 79 5, 82 3, 83 2		(1934)	81 1,

Book Notices

Silicosis and Asbestosis By Various Authors Edited by A. J. Lanza, M.D, Assistant Medical Director, Metropolitan Life Insurance Company Cloth. Price, $4 25 Pp 439, with 59 illustrations. New York, Toronto & London Oxford University Press, 1938

For the past ten years this country has seen marked scientific interest in the dusty lung diseases. This has led to numerous publications, trials, conflicting testimony, legislative enactments, theories and alleged palliatives. Slowly there emerge the significant facts This book is a record of the accrued substantial observations made with regard to the two chief dusty lung diseases, silicosis and asbestosis. Its able editor, rather than author, Dr. Lanza, participated in the first well planned investigation of silicosis in this country near the year 1915, carrying out activities in the tristate lead and zinc mining district in the vicinity of Joplin, Mo. Other contributors are Drs. Sayers, Prendergrass, Gloyne, Gardner and Middleton. All have participated extensively in many investigations of dusty lung diseases. They discuss the history of silicosis and asbestosis, clinical aspects, x-ray diagnosis, chemical and experimental pathology, preventive measures, legislation, public health and economic aspects. While all sections are meritorious, the lengthy chapter on x-ray diagnosis is especially well presented. During the turmoil centering about dusty lung diseases for the past ten years it has been necessary often to make apologies for the medical profession for lack of familiarity with silicosis and later with asbestosis. Now the lament can no longer be made that in the English language there is no reliable comprehensive medical presentation on dusty lung diseases.

The printing is not as good as the contents. Several pages intended to be printed are left blank. Some lack of uniformity in the arrangement of the sections exists. Spacing, such as that in the table of contents, is poorly arranged. The repetition of the various titles of the authors in each chapter heading is superfluous In general the contents reflect to a high degree the art and science of medicine, but the make-up is not an equally good example of the art of printing.

La fluorescence en biochimie. Par Ch Dhéré, professeur de physiologie à l'Université de Fribourg (Suisse). Paper. Price, 80 francs Pp 318, with 108 illustrations. Paris: Les Presses Universitaires de France, 1937.

The first three chapters give a fairly inclusive treatment of the fundamental principles of fluorescence, of its demonstration and of the apparatus and methods for recording and measuring it. A brief chapter covers the fluorescence of carbohydrates and glucosides as well as the changes in fluorescence in the treatment of simple carbohydrates with the common reagents such as bases, acids and furfural indicators. Chapter V briefly covers pure

Thalassa: A Theory of Genitality. By Sandor Ferenczi, M.D. Authorized translation from the original German version entitled Versuch einer Genitaltheorie, by Henry Alden Bunker, M.D. Cloth. Price, $1.75. Pp. 110. Albany, New York: The Psychoanalytic Quarterly, Inc., 1938.

The German volume from which this book was translated was published in 1923 but was conceived and written between 1914 and 1919, during the war, in the author's leisure time. It is important to stress the time element, since it dates the expressed ideas to a period of psychoanalytic development which, in the short life of that science, was decidedly early. The work is a product of a time when psychoanalysis was concerned with metapsychologic speculations and was far removed from biology and medicine. The author has attempted to base his theory of genitality on biologic data and phylogenic concepts by analogy, and his speculations are highly provocative. The work is an extremely interesting and fascinating speculation but indicates the need for development of a method other than that of analogy to link biology and psychology. The fundamental premise is a lamarckian concept of evolution on which teleologic bases of evolution interpreted from psychology rest. Biologists should by all means be acquainted with this book.

Internal Medicine in Dental Practice. By Bernard I. Comroe, A.B., M.D., F.A.C.P., Instructor in Medicine, Schools of Medicine and Dentistry in the University of Pennsylvania, Philadelphia, Leon H. Collins, Jr., A.B., M.D., F.A.C.P., Associate in Medicine in the University of Pennsylvania School of Medicine, Philadelphia, and Martin P. Crane, B.S., M.D., Instructor in Medicine in the Schools of Medicine and Dentistry of the University of Pennsylvania, Philadelphia. Cloth. Price, $4. Pp. 352, with 45 illustrations. Philadelphia: Lea & Febiger, 1938.

This book has been written primarily for dentists and dental students, presenting the necessity of close collaboration between dentist and internist, as stated in the introduction: "Dentists frequently are afforded the opportunity of observing manifestations of systemic disease in individuals before these patients seek medical aid." There seems to be an underlying motive to interest the dentist in public relations work for the physician with a hope that the general public may come to appreciate a necessity of frequent physical examinations. There is little or no reference to the help a physician might be to a patient by observing foci of infection in the mouth and directing the patient to have dental attention. The text is written in clear, concise and convincing style, treating systemic diseases in twelve parts. Each part has a well planned medical summary describing specific diseases and their manifestations in the oral cavity. In each part adequate references are listed, so that more detailed information may be obtained if desired. This book should be of real value to dental schools as an accessory textbook.

Die Therapie der Thrombose. Von Dr. Ernst Friedländer. Paper. Price, 5.40 marks. Pp. 117, with 27 illustrations. Leipzig & Vienna: Franz Deuticke, 1938.

The author reviews the anatomic and pathologic aspects of thrombosis. He concurs in the view that emboli are derived from fresh thrombi and that those which occur in the third week following venous thrombosis result from newly formed thrombi. While he has established anatomic considerations well, certain physiologic conclusions lack the necessary evidence, for example that the femoral vein may be empty in a bedridden patient. The fact that in the prone position the blood travels in the femoral vein up a 34 per cent grade is important in the genesis of thrombophlebitis. The etiology of venous thrombosis is extensively reviewed but no new contributions are made. The author's main objectives in the management of thrombophlebitis are fixation of the thrombus and restoration of circulation. He believes that ambulatory patients with phlebitis should remain ambulatory and that patients confined to bed when phlebitis occurs should be put through a series of positions and graduated exercises. He believes that his method of treatment reduces the incidence of pulmonary embolism but it is to be regretted that there is not good proof of this. He stresses the danger of pulmonary embolism after thrombophlebitis, yet it has been emphasized in the American literature that embolism seldom follows phlebitis. A recent article states that thrombophlebitis was recognized clinically in only five of 116 consecutive cases of fatal postoperative pulmonary embolism. It is doubtful that the complicated exercises outlined are necessary, for patients appear to convalesce satisfactorily from phlebitis if they remain in bed with the involved leg elevated and warmed by moist packs until the tenderness over the inflamed vein has disappeared, the oral temperature has returned to normal and the edema has disappeared. The author states that with his method of treatment the average period of disability has been reduced from seventy-six to six days. The former figure is considered archaic in this country, since most patients become ambulant from eighteen to fourteen days after the onset of phlebitis when given much simpler treatment than that outlined. If one considers the mental and physical comfort of the patient in addition, the value of the author's management remains doubtful. The monograph suffers from repetition and theorization. Its chief value is in reviewing the subject of thrombosis and reemphasizing that it is not necessary to keep patients with thrombophlebitis in bed for long periods.

Synopsis of Clinical Laboratory Methods. By W. E. Bray, B.A., M.D., Professor of Clinical Pathology, University of Virginia, Charlottesville. Second edition. Fabrikoid. Price, $4.50. Pp. 408, with 68 illustrations, including 17 color plates. St. Louis: C. V. Mosby Company, 1938.

Two years ago the first edition of this excellent synopsis appeared. It had 324 pages, contained descriptions of the most frequently used laboratory tests and was well liked by physicians and technicians. In the second edition it has been enlarged but the arrangement of the chapters has remained the same. More attention has been given to the clinical significance of laboratory observations. The descriptions of the various procedures are brief but adequate. The black and white illustrations have been increased from thirty-two to fifty-one and the color plates from eleven to seventeen. Additional methods described include the determination of serum phosphatase, titration of staphylococcus antitoxin, use of the peroxidase Giesma stain, cough plate method for the diagnosis of whooping cough, vitamin C titration, test for cyanates in the blood, determination of sulfanilamide in the blood and differential heterophil agglutination for infectious mononucleosis. There are chapters on poisons and foreign substances and on surgical pathology and one listing indicators, stains and reagents. This manual is one of the best small books on laboratory diagnosis.

Nogle Undersøgelser over Nyrefunktionen ved Epilepsi. Af Alf. Yde. [Studies on Renal Function in Epilepsy.] Denne Afhandling er af det lægevidenskabelige Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad, København. Paper. Pp. 136. Copenhagen: NYT Nordisk Forlag, Arnold Busck, 1937.

This is a doctorate thesis based on extensive personal investigations of every phase of renal function in epileptic subjects observed in the university psychiatric clinic of Copenhagen and the epileptic colony "Filadelfia." Among the conclusions are that there is no definite relationship between diuresis and the epileptic attack. The author has been unable to confirm the hypothesis of preparoxysmal oliguria and postparoxysmal polyuria. The urea clearance rises above the normal upper limit for some hours before an attack and falls suddenly after the attack. It is suggested that the preparoxysmal rise may be caused by central irritation brought about by a moderate increase in epinephrine, while determinations of the chlorine in the plasma and urine did not lead to its explanation. Finally, it is concluded that functional alterations in the vegetative centers in the midbrain play a part in the precipitation of epileptic attacks.

Practical Birth-Control Methods. By Norman E. Himes, Ph.D. With the medical collaboration of Abraham Stone, M.D. Introduction by Robert L. Dickinson, M.D. Foreword by Havelock Ellis. Paper. Price, 95 cents. Pp. 254, with 29 illustrations by Irving Geis. New York: Modern Age Books, 1938.

In this book, written in a simple pleasant style, birth control and allied subjects are discussed in a comprehensive manner denoting the authors' thorough understanding of this vital problem. The medical aspects of contraception are ably presented together with effective anatomic diagrams for instruction purposes. Common misconceptions and causes for failures of the various methods are explained clearly. The book is replete with many practical details, often neglected, which are of considerable importance in the teaching of contraception. There are a number of interesting topics other than the medical aspects which are educational: legal aspects, abortion, history of contra-

ception, sterility and other subjects are presented clearly in nontechnical language. An admirable feature of the book is the discussion of the social, economic and religious backgrounds of the individual in respect to the practice of contraception. These environmental factors are intimately involved in the majority of problems, and the authors are to be complimented on the sympathetic and reasonable handling of these subjects. An informative appendix adds to the value of the book.

Les maladies de l'œsophage. Par J. Terracol, professeur à la Faculté de médecine de Montpellier. Avec la collaboration de J. Baumel et al. Cloth. Price, 220 francs. Pp. 664, with 352 illustrations. Paris: Masson & Cie, 1938.

At first thought it would seem improbable that any one could write a book of 664 pages on the esophagus alone, but actually Dr. Terracol and seventeen collaborators have done the trick. What is even more remarkable is that an examination of certain chapters, such as the one on cardiospasm, reveals that a good deal more might well have been written. In fact, the main criticism one might bring against the book is that so little is written about the treatment of cardiospasm, which is the most common disease of the esophagus. The authors seem never to have heard of the Plummer dilator, which works beautifully in most cases, and they give some space to a discussion of the old transabdominal operation, which should probably never be used. Certainly if this book goes into a second edition the authors should describe the Plummer-Vinson technic and should show the tremendous advantages of passing the dilating instrument over a thread which has previously been swallowed and allowed to pass down into the small bowel, where it is in a way anchored. Another criticism that might be directed against the book is that in places the authors might have done better to describe only the treatments which they have found useful. It only clutters up the literature to describe those which are of little if any value. These criticisms, however, should not be allowed to obscure the fact that the book contains a tremendous amount of information presented in an attractive way. Every medical library of any size should have a copy. It is well illustrated and there are some colored plates showing the esophagus as seen through the electrically lighted tube. There are good bibliographies attached to the chapters, but unfortunately there is no index.

Aids to Embryology. By Richard H. Hunter, M.D., M.Ch., Ph.D., Lecturer in Anatomy, Queen's University, Belfast. Third edition. Cloth. Price, $1.25. Pp. 178, with 44 illustrations. Baltimore: William Wood & Company, 1938.

Here is a series of brief summaries to each of which a still briefer summary is appended. The object is to provide clear and concise statements which can be memorized and used to answer questions in examinations. In this edition discussions on heredity and the current ideas as to the endocrine regulation of the female reproductive system have been added to meet new requirements of the British Medical Council. The author hopes too that he has provided enough information so that the student can take a rational and understanding view of congenital abnormalities. It is probable that the student cannot assimilate much more embryology than this unless he can come into personal contact with some of the kaleidoscopic changes of ontogeny. Often the treatment is necessarily so inadequate as to give no ideas whatever (see coelom); there are merely some pertinent phrases which may enable the student to indicate that he has heard mention of the subject in question. Some quite unnecessary mistakes have crept in, especially in the chapter on the nervous system. In an appendix there is a discussion of fetal age, with data on the time of appearance of certain ossification centers and a list of characters which can be used to estimate the age of viable fetuses.

Vom Wesen der Neurose und von ihren Erscheinungsformen. Von Dr. Ernst Speer, Nervenarzt in Lindau (Bodensee). Paper. Price, 3.60 marks. Pp. 122, with one illustration. Leipzig: Georg Thieme, 1938.

Neuroses are never permanent states in the sense of inherited and unmodifiable characteristics but always follow disturbances in assimilating and reacting to life experiences. They are partial solutions to the experience and as such indicate the possibility within the person of a satisfactory terminal solution. Neuroses are not due to structural abnormalities of the brain, either histopathologic or chemical, nor are they the results of extrapersonal demoniacal agents. The individual, furthermore, is guiltless in his illness. No neurotic consciously develops his difficulty; the neurosis develops from the unconscious. These excerpts are evidences of the dynamic concepts of the author, remarkable only because of their source. This is one of the few books that indicate a discontent with the official constitutional, racial concept of nervous disorders expressed in recent German publications. The author expresses his point of view delicately without too great detail. Concerning the early life experiences which are not successfully solved and which remain unconscious, manifesting only the partial solution in neurotic behavior, he is reticent. Nevertheless the work is a hopeful sign indicating that dynamic psychiatry in Germany is not dead but only suppressed into latency.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Compensability for Disability Following Hernia and Operative Repair.—The claimant's work required him to shovel dirt and other substances from one place to another. He alleged that on May 19, 1936, while so engaged, a hernia appeared suddenly and was immediately followed by intense pain. Previous to that time, according to his claim, he had been in sound physical condition. On June 1, he filed a claim with the industrial accident board but said nothing concerning the operation to cure the hernia that he was to submit to on the following day. The claim did not reach the board until the day after the operation, but the board was notified of the operation about July 10. After a hearing on August 12, the board held that the operation had cured the hernia and awarded compensation at the rate of $7.20 a week for twenty-six weeks for temporary disability. The claimant alleged that he had been permanently and totally disabled and appealed to the district court, Wise County. After a jury trial, the court rendered judgment in his favor for $2,492.48. The employer's insurance carrier thereupon appealed to the court of civil appeals of Texas, Amarillo.

The insurance carrier contended that the operation for the repair of the hernia had been successful and that the claimant was entitled to compensation for only temporary disability, under subdivision 4, section 12 b, article 8306, Revised Civil Statutes of Texas, 1925, which authorized compensation for twenty-six weeks only, after a successful operation for hernia. Clearly, however, said the court, if the operation failed to restore the appellee to his former ability to perform labor, it would not be a successful operation such as was contemplated by the statute. It was proved by ample evidence that the operation had reduced the hernia and that the complainant had completely recovered from the operation. He claimed, however, that notwithstanding the operative cure he had "a left-over condition from the injury and operation which rendered him totally incapacitated to perform labor." The question therefore, said the court, was whether or not the operation had failed to restore the appellee to his former ability to perform labor. The statute does not require an injured employee to file his claim for anything other than a hernia, and when he has received an injury to a specific member of the body he is not confined to a recovery of the compensation specially provided for such injury if he alleges and proves other injuries, or if it is fairly shown that the injury to the specific member of the body has involved other portions of the body or affected his general health.

In the claim filed by the claimant with the industrial accident board he stated that the front of the abdomen near the left groin, the site of the injury, was swollen, that he was unable to stand on his feet without intense pain and that the injury had resulted in permanent and total disability. A physician testified that he had examined the claimant and that when the claimant walked he had to do so very carefully in order to prevent pain; that he could not straighten his body very well

ior hold himself in a straightened position; that the claimant vas very much weakened; that the condition would last as long s he lived and that the claimant could not do anything. There vas no evidence to show that the claimant's condition was due o anything other than the injury that he received May 19. It vas proper, therefore, said the appellate court, for the trial ourt to submit to the jury the question as to whether the laimant had sustained any loss of capacity to work as the result f the injury.

The insurer complained that the trial court had refused to ubmit to the jury a special issue requested by it, asking the ury to find from a preponderance of the evidence that the laimant's disability would not be removed by physical exertion. 'he request for this special issue was based on the testimony f a medical witness to the effect that after an operation for ei nia a patient becomes "soft" to the extent that when he goes ack to work he has considerable soreness; that if the claimant vould go back to work and perform physical labor for ten ays or two weeks the soreness of which he complained would ntirely disappear, but as long as the claimant refrained from 'orking and exercising the muscles and tendons in the area of ne operation he would experience tenderness and the muscles nd tendons would be sore. The trial court refused, however, o submit that issue. The testimony of the witness, said the ppellate court, was necessarily only his opinion. The jury ould not have known whether exercise would or would not emove the disability. If the jury had undertaken to answer uch a special issue, their answer could have been nothing more ian their opinion obtained from the testimony of the surgeon s to the probability of a future event, which would not have urnished a proper basis for a judgment in a case of this kind. f the insurer desired that the jury pass on the question pre- ented by the requested special issue, the proper course would ave been for it to request an examination of the claimant, on ie theory that he was persisting in injurious practices which ended to imperil or retard his recovery. If an examination had een made under such circumstances and the evidence in respect iereto had warranted, it would have been proper for the court o submit such an issue as to whether or not the appellee was ersisting in such practices. The trial court, therefore, did not rr in refusing to submit to the jury the special issue requested y the insurer.

The court of civil appeals accordingly confirmed the judgment i favor of the claimant, but only on condition that he consent o a reduction of the award by $100, the amount allowed as the hysician's fee in the case. This reduction was based on the act that the claimant had not submitted evidence in the course f the trial as to the reasonableness of that fee.—*Travelers Ins. 'o. v. Mote (Texas), 116 S. W. (2d) 427.*

Evidence: Hypothetical Question Must Be Based on 'acts in Evidence.—The testimony of a physician, said the upreme Court of South Carolina, that in his opinion the plain- ff was totally and permanently disabled can have no probative alue in the face of evidence of the physical fact that the plain- iff was able, after he was alleged to be disabled, to perform the ame sort of work in which he was accustomed to engage. 'urther, the hypothetical question propounded to an expert itness must be framed only on facts in evidence and must not iclude the opinion of another expert As is said in 22 Corpus uris 706-9:

> The expert, properly so called, is asked what would be his judgment pon all or any prescribed part of the facts, as to which evidence has been awfully received, or which has been admitted, assuming that they are ue, provided that a sufficient number of facts are assumed to enable ie witness to give an intelligent opinion The witness having no facts i mind as the result of observation, it is in this way alone that a proper asis for a reasonable judgment can be furnished, and the witness cannot dd to the hypothetical question facts within his own knowledge *and not s evidence.* The requirement that the question should be in hypothetical orm, *stating fact of which there is some evidence in the case, continues* roughout the examination of the expert, . . Different hypotheses ay be submitted to the witness for different parties, *provided the facts nbraced in each hypothesis have some support in the evidence* . . . hypothetical question which includes, with other facts, the opinion of nother expert is improper.

—*Ellis v. Kansas City Life Ins. Co. (S. C.), 197 S. E. 398.*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Ophthalmology, St. Louis

22: 119-238 (Feb.) 1939

Histologic Study of the Eyes of Rabbits Congenitally Infected with Syphilis. H. Shiga, Tokio, Japan.—p. 119.

Late Results in Retinal Detachment Operations. D. K. Pischel, San Francisco.—p. 130.

Papillitis and Papilledema in Multiple Sclerosis. S. Sugar, Chicago.—p. 135.

Dysostosis Craniofacialis (Crouzon). A. C. Krause and D. N. Buchanan, Chicago.—p. 140.

Lectures on Motor Anomalies: VI. Principles of Surgical Treatment. A. Bielschowsky, Hanover, N. H.—p. 145.

Some Physiologic and Anatomic Aspects of the Cornea Affecting Its Pathology. T. L. Terry, Boston.—p. 153.

Monocular Protection versus Monocular Occlusion. W. H. Howard, Chicago.—p. 156.

Superficial Marginal Keratitis: Clinical and Anatomic Findings in Fellow Eyes. O. H. Ellis, St. Louis.—p. 161.

Congenital Abducens Paralysis. C. Apple, Chicago.—p. 169.

American Journal of Pathology, Boston

15: 1-154 (Jan.) 1939

Pathologic Anatomy of Experimental Thrombopenic Purpura in the Dog. L. M. Tocantins and H. L. Stewart, Philadelphia.—p. 1.

Pathologic Changes in the Heart, Skeletal Musculature and Liver in Rabbits Treated with Insulin in Shock Dosage. J. Tannenberg, Albany, N. Y.—p. 25.

Growth Processes in Cartilage and Bone Subsequent to Gonadectomy and Administration of Anterior Pituitary Extract of Cattle in Immature Male and Female Guinea Pigs. M. Silberberg and Ruth Silberberg, St. Louis.—p. 55.

*Observations on Etiology of Ulcerative Colitis: III. Distribution of Lesions and Its Possible Significance. R. Lium and J. E. Porter, Boston.—p. 73.

Polyarteritis Nodosa: Report of Case. D. R. Weir, Boston.—p. 79.

Metastasizing Fibroleiomyoma of Uterus: Report of Case and Review of Literature. P. E. Steiner, Chicago.—p. 89.

Primary Hyperparathyroidism with Extensive Renal Calcification and Secondary Hyperplasia of the Parathyroids: Report of Case. J. W. Johnson Jr., New York.—p. 111.

Tularemic Septicemia: Report of Case. P. Kimmelstiel and H. W. Caldwell, Richmond, Va.—p. 127.

Congenital Rhabdomyoma of Heart: Report of Case. J. S. Labate, New York.—p. 137.

Method for Impregnation of Perivascular Nerves on Intracerebral Blood Vessels. S. P. Humphreys, Montreal.—p. 151.

Ulcerative Colitis.—Of six cases of ulcerative colitis that came to necropsy, Lium and Porter state that the first attack of colitis occurred in two only two months before death. Four of the patients had had previous attacks and died during an acute exacerbation of the disease. Cultures of stools and agglutination reactions for dysentery organisms of five of these patients were negative. The cultures of stools for pathogenic bacteria were repeatedly negative of one but Bacillus enteritidis was recovered from the blood stream at necropsy. The disease varied in its extent; one patient showed involvement of only the rectum and sigmoid, in three the lesions extended to the splenic flexure and in one to the midportion of the transverse colon, and one showed involvement of the entire colon without extension beyond the ileocecal valve. In all instances the most severe lesions were in the rectum. At the junction of the rectum and sigmoid the ulcerations developed into three rows running in the longitudinal direction of the intestine. In places the ulcerations extended between the longitudinal rows of ulcers and when this occurred they seemed to follow a linear pattern in the circular direction of the intestine. When the fat and mesenteric attachments were dissected away from the muscular layers of the intestine it was found that the lesions lay directly over the tenial bands. This correlation was found in all six cases. The intestinal tract was unevenly involved by the disease and lesions were found in all stages of development in the same individual. The earliest gross changes observed consisted essentially of hyperemia, edema and petechial submucous hemorrhages. In certain areas in which the lesions had advanced to a later stage, superficial erosions occurred which were covered with fibrin. Other lesions were found which were interpreted as transitional stages between the earliest erosions and the frank ulcerations. Mucus in the epithelial cells was completely or almost completely absent from the early lesions. This was observed in all sections taken from the acutely involved areas and contrasted sharply with the appearance of the mucous membrane in a normal colon. The arrangement of the severest lesions in ulcerative colitis is such that they lie directly over the most powerful muscles, and there may well be a direct relation between the muscles and the lesions. The early stage of ulcerative colitis can be simulated experimentally in animals by hypermotility and spasm of the colonic muscles. Spasm and hypermotility of the intestinal muscles are a prominent clinical feature of ulcerative colitis. It seems highly probable that ulcerative colitis is primarily a disease caused by intense muscular spasm and hypermotility, and therefore the distribution of lesions follows a muscular pattern. Whatever infectious element is present may well be due to secondary involvement of the damaged areas caused by muscular overactivity.

Progress in the Design of Rotating Anode Tubes. M. J. Gross and Z. J. Atlee, Chicago.—p. 276.

Radiotherapy in Hodgkin's Disease.—Gilbert finds that x-ray exploration of malignant granulomatosis (Hodgkin's disease or lymphogranulomatosis) offers a valuable means of orienting clinical diagnosis, of determining the site and extent of certain deep lesions, and of verifying and following their regression after treatment or their extension after recurrence. Systematic roentgen therapy is the method of choice because, by reason of the essentially lymphoid character of its lesions, malignant granulomatosis usually has an exceptional degree of radiosensitiveness. The diagnosis should rest on a biopsy whenever possible. In this systemic disease the roentgenologist giving roentgen therapy must act as a general physician. He should know its manifestations, the regions it involves, its modes of extension, its types and evolutionary caprices, its response to roentgen therapy and the reactions of the patient during treatment. The aim of treatment is to obtain as frank and as long remissions as possible, thus restoring to the patient the illusion of recovered health and complete capacity to work. This implies the destruction of all the granulomatous foci, deep and superficial, without jeopardizing the general condition of the patient or the condition of the blood. Except in special cases, roentgen therapy is more important than radium therapy because of the extent of the area to be irradiated and because of the doses to be delivered to the deepest foci. Simple, daily, fractional irradiation should be directed to each invaded region in succession or, according to the cases, directed first to regions requiring the

earliest treatment. In this way each field is irradiated only at intervals of about two days until a sufficient total dose has been given (clinical and blood examinations). Roentgen therapy should be repeated only on the recurrence of the disease. So-called maintenance or prophylactic treatment is superfluous and even detrimental. Roentgen therapy modifies the clinical aspect of the disease and retards its evolution. Its influence is the more pronounced as the disease is less malignant; its extent and the age of the patient also are deciding factors. The average duration of survival, according to different authors, has been doubled and even tripled; the same proportion is found when long term results are analyzed.

Carcinoma of Duodenum.—Lieber and his co-workers present a clinical and pathologic review of carcinoma of the peripapillary region of the duodenum, based on seventeen new cases and 205 cases reported in the literature. Thirteen of the authors' cases and one from the literature were found in 22,152 necropsies and three in 4,154 necropsies. The average age was about 54.4 years. Eighty-three of the patients were women and 139 were men. Only thirteen cases occurred in individuals from 15 to 34 years of age. The onset was acute in about 80 and gradual in 20 per cent of the cases. The principal symptoms and signs, irrespective of the mode of onset, were jaundice, pain, loss of weight and strength, anorexia, fever, vomiting, constipation, diarrhea and a sense of weight and pressure in the abdomen. Other less common symptoms were dyspepsia, epigastric distress, flatulence, abdominal distention, nausea and chills. Jaundice was a symptom in 98.2 per cent of the cases and pain in 59.4 per cent; both were associated at the onset of the condition in 24.3 per cent. Fever, sometimes accompanied by chills, occurred in 33.3 per cent of cases, usually late in the condition. A mass was palpable clinically in the region of the primary tumor in only four cases. The liver was palpably enlarged in 77.9 per cent of cases and the gallbladder in 49.9 per cent. A moderate grade of anemia was the rule in these patients. A correct preoperative diagnosis was made in approximately 17.1 per cent of cases. The presence of a lesion in the region of the papilla of Vater was recognized roentgenographically in sixteen of sixty cases examined. At celiotomy, a correct surgical diagnosis was made in approximately 68 per cent of 122 cases. Ninety-seven of 100 patients, treated medically and not subjected to surgery, died on an average of 6.63 months after the onset of the illness. Surgical therapy was instituted in 122 cases. There was an ultimate mortality rate of 72 per cent. The operative mortality was 50.6 per cent. Of fifty-one patients subjected only to some type of palliative procedure for the relief of obstructive jaundice, the operative mortality was 78.4 per cent. Of fifty-seven patients in whom the primary growth was resected either alone or in combination with other surgical procedures, the operative mortality was 30 per cent. The patients who died immedately after an operation were ill for an average of six months before operation. Other patients who were operated on and who survived the immediate postoperative effects lived for an average of two years after the onset of the condition, and a little more than one half of these were reported alive at the end of this period; of this group, those who died were ill for an average of seven months before operation, whereas those reported as still living were ill for an average of only two months before operation. These figures emphasize the importance of early diagnosis and early surgical treatment.

Diseases of Metabolism and Nutrition: Review of Certain Recent Contributions. R. M. Wilder, D. I. Rutledge, Rochester, Minn., and D. L. Wilbur, San Francisco.—p. 356.

Abnormalities of Calcium Metabolism.—Taylor and his associates point out that faulty calcium metabolism accounts for a wide range of discomforts and disabilities and in some of its forms leads to untimely death. Calcium is deservedly a central figure in mineral metabolism. Americans ingest too little calcium salt. The body does not naturally conserve calcium. If there is a shortage in the supply of calcium or if there is an increased demand for it, excretion proceeds without economy and the organism is confronted with a progressive deficiency. Oversupply of calcium is probably never a practical problem in human beings. In persons with abnormal deposits of calcium salt, the problem is one of perversion of distribution and not one of excessive intake. The authors believe that one should suspect disturbance of mineral metabolism when there is defective nutrition. A child of subnormal stature may have congenital renal insufficiency, with a fault in the excretion of phosphate, as in renal rickets. A thin woman with diarrhea may be losing calcium, to the disadvantage of the function of the soft tissues; tetany may develop. A poorly nourished person with anemia may have poor absorption of iron or of calcium from the digestive tract. The food eaten may contain too little of these elements. Unusual fractures may be due not only to primary or secondary osseous neoplasm but to poor internal economy of calcium or of phosphate. A tonic convulsive state may be due to a lowered calcium content of the serum. Convulsions may result from both uremia and low calcium values. A high calcium content may cause or predispose to an abnormally slow cardiac rate or to rapid, irregular cardiac action. These effects were seen in a patient with a high calcium content secondary to metastatic carcinoma of bone. Not all spurious deposits of calcium salt are traceable to overabundance of calcium in the blood. In calcinosis and several allied diseases the calcium and phosphate contents of the serum are normal. For some reason there are points of diminished tissue viability in these conditions. Defective local circulation may be the reason. These regions become progressively buried in calcium salt. In cases in which bone is abnormally rarefied phosphatase is often present in the serum to excess. In Paget's disease, phosphatase is present in the bone in less than normal amount. When there is a suspicion of deranged mineral metabolism, the important facts can usually be obtained at the bedside with the aid of the laboratory and x-ray facilities in a class A hospital.

Gastroscopy in Pernicious Anemia.—Schindler and Serby made gastroscopic studies of twenty-three patients with pernicious anemia; nine were seen before any treatment had been given, fourteen after adequate treatment and three before and after treatment. All untreated patients presented superficial gastritis, superficial plus atrophic gastritis or patchy or diffuse

atrophy. No definite improvement of the condition of the gastric mucosa was found in four cases after treatment, atrophy definitely progressed in one, the mucosa of the antrum was found to be normal in seven, there was almost complete regeneration in one, and all portions of the gastric mucosa became normal in four cases. These facts can be explained only by the assumption that two separate diseases of the stomach are present in pernicious anemia. Primarily there is dysfunction of the cells which produce the "antianemic" factor. Secondarily there follows degeneration of the surface epithelium, with superimposed genuine inflammation, which may or may not heal when the deficiency is eliminated. The secondary inflammation is usually combined with a similar disorder of the tongue and of the intestine, with dysfunction of the hemopoietic apparatus and combined degeneration of the spinal cord. However, the absence of the "antianemic" factor may sometimes lead to severe but reversible atrophic gastritis, without diseases of the blood. Atrophic gastritis may be due in many cases to some kind of deficiency and in some to the lack of the "antianemic" factor. This disease should be diagnosed by the use of the gastroscope. A gastroscopic check-up on the effects of therapy is necessary. The frequent incidence of mucosal polyps of the stomach in pernicious anemia has been corroborated.

Cylindroma of Upper Air Passages: Cylindromatous Type of Mixed Tumor. R. Kramer and M. L. Som, New York.—p. 356.

Suppuration of the Petrous Pyramid.—Lillie and Williams report six cases of chronic suppuration of the petrous pyramid; a presumptive diagnosis was made in five after careful consideration and integration of symptoms and signs. The diagnosis was confirmed by an operation directed primarily to the petrous pyramid. If discharge from the ear, low grade sepsis and deep retro-ocular pain, which were absent, had been insisted on as the cardinal symptoms and signs, the diagnosis would have been missed entirely. The six cases exemplify different pathologic processes, ranging through caseated abscess and meningitis to thrombosis of the cavernous sinus, meningitis and rupture into the nasopharynx. Two were cases of encapsulated chronic petrositis without apparent otitis media. While it is not comforting to think of apparently healed mastoiditis or petrositis becoming active again after a period of five or ten years, nevertheless it can do so. In certain cases in which there is an obscure clinical syndrome referable to the head, the history of aural disease may assume a place of great importance in determining the lesion causing such a syndrome. The cases presented show the futility of attemping to fit clinical material into didactic or academic pigeonholes. If exploratory operation had not been instituted before the appearance of complete symptoms and signs in the six cases, the result (five recoveries) might not have been so favorable. This group of cases demonstrates to the authors that it is necessary to approach the petrous pyramid without preconceived ideas regarding the surgical technic that will be adequate for the control of the disease encountered.

Protection of Skin Against Ultraviolet Rays.—Bachem and Fantus studied the protective properties against sunburn of several materials by spectroscopic examination and cutaneous tests. From cutaneous tests they find that tragacanth paste is worthless as a protectant against sunburn, that vanishing cream, cold cream and white petrolatum are relatively much less effective than are mixtures of yellow petrolatum and wool fat petrolatum, cream salve and diachylon ointment. The cream salve tested gave the best result. This is an emulsion produced by the addition of about 50 per cent of water to a mixture of one part of wool fat and three parts of petrolatum. Its particular value is no doubt explainable by diffusion, reflection and absorption phenomena. Of the insoluble powders studied, titanium dioxide is the most efficient in its protective value and calamine is next in order. Barium sulfate and esculin were less efficient. Of soluble substances that gave promise of being useful as sunscreens ichthammol, leukichthol, caramel, quinine oleate and menthyl salicylate were tested; 2 per cent ichthammol was about as efficient as 4 per cent caramel (sugar coloring) or 5 per cent menthyl salicylate. Quinine oleate was not found to be as efficient as ichthammol and the other substances. As a sunburn protectant is applied to surfaces of the skin exposed to view, cosmetic quality of the preparation is essential. The authors therefore decided to take advantage of the "cuticolor preparations" developed by Fantus and Dyniewicz. "Cuticolor titanium dioxide" is made with titanium dioxide, which has been found to be the most efficient of the powders tested. To give this white powder a skin color, red ferric oxide (6 per cent) and yellow ferric oxide (8 per cent) are added. Rose water is employed to give it a pleasant odor. Such volatile oils as bergamot, lime, lemon, orange and cologne have photosensitizing qualities and should be avoided in sunscreens. The comparison of cuticolor ointment with various proprietary preparations on the market recommended for protection against sunburn shows that "cuticolor ointment" is superior to any of them and a test exposure of an individual to actual sunburn shows that cuticolor ointment is indeed efficient in a practical test. Formulas for six sunscreen preparations are listed any one of which, the authors say, has been found superior to a number of proprietary sun protectants on the market.

Roentgen Treatment of Gas Gangrene.—Kelly and Dowell believe that early and frequent treatment with small doses of roentgen radiation is the answer to the prevention or treatment of infections with gas forming organisms. They sent out questionnaires to about 100 physicians scattered throughout the United States and Canada from whom they obtained data on 143 cases (including their own). From the results obtained in these cases as compared with past experiences the authors are positive that x-radiation will lower mortality and lessen the necessity for amputation. The mortality rate alone is no longer a gage of successful treatment of gas gangrene and they suggest that in the future the number of amputations as well as the deaths be included in reports concerning methods of treatment in this group of infections. An analysis of the cases reveals that only the severely affected patients will die in spite of x-radiation. Accordingly, treated properly no patient should die of pure gas gangrene but rather from other causes. When it is considered that it is the severely injured, senile or debilitated patients in whom gas gangrene develops, it is realized that the primary disease, without the complication of gas gangrene, presents a variety of handicaps which in themselves will cause death in from 3 to 7 per cent of all cases. The unfortunate

individual in whom gas gangrene develops after a hypodermic injection is an exception to the seriously injured or senile patient. Unexplained pain, swelling or fever following the injection calls for an x-ray examination to establish the presence of gas, in which case roentgen treatment is imperative.

Relation of Immunizing Dose of Influenza Virus and Immunity.—Francis finds that a direct proportion exists between the concentration of epidemic influenza virus used for intraperitoneal immunization of mice and the degree of immunity to intranasal infection which develops. Mice vaccinated with virus of a given strength resist infection with virus of the same concentration but not more. The fact that there exists a limiting threshold for the degree of immunity which a certain strength of virus will induce indicates that the virus does not multiply after intraperitoneal inoculations. In ferrets a state of partial immunity is induced as a result of subcutaneous vaccination with active influenza virus. Vaccination with doses containing 100 or more intranasal infectious units is required for the production of circulating antibodies. Intranasal inoculation with one infectious unit results in a firm, immediate immunity, although the duration of immunity may bear a relation to the severity of the original infection and consequently to the size of the infecting dose. Ferrets in a state of partial immunity resulting from subcutaneous vaccination or from infection respond to intranasal inoculation of influenza virus with an accelerated production of neutralizing antibodies. The antibody titer under these conditions reaches a much higher level than occurs following a primary infection. Fully immune animals show no further antibody response to a second inoculation.

Ethyl Carbamate in Treatment of Asthma.—During the last eighteen months Farmer has used ethyl carbamate as an antispasmodic in thirty cases of bronchial asthma. It was administered orally to adults in doses of from 1 to 2 Gm. (dissolved in water). Not more than 4 Gm. was given in any one day or for longer than four or five consecutive days. No untoward effects were observed. In fourteen of the thirty cases the alleviating action, which sets in after from fifteen to thirty minutes and lasts several hours, was most satisfactory.

Effects on Normal Stomach of Aluminum Hydroxide Gel.—According to Quigley and his associates, the administration of aluminum hydroxide gel in massive doses (120 cc. daily) for seventy-nine days to normal dogs was without significant effect on the gastric evacuation time or the histologic structure of the gastric tissue, and it only transiently reduced the gastric secretory response of free acid to histamine. Balloon records showed that quantities of aluminum hydroxide within the clinical range failed to produce a significant change in the motility or the tone of the stomach or pyloric antrum. These records were made while the medication was being introduced into the stomach or duodenum. It is believed that the therapeutic action of aluminum hydroxide depends largely on its buffering action on gastric acid and on significant modifications in gastric evacuation and secretory activity seen in the presence of ulcer or other pathologic changes but not in the normal intestine.

Torula Infection of the Central Nervous System.—Since October 1935 Magruder has observed three instances of torula involvement of the central nervous system. Case 1, on admission, presented a clinical picture resembling intracranial tumor. After careful neurologic, laboratory and x-ray studies the diagnosis was unsuspectingly made by culturing the yeastlike organism from the spinal fluid. The organism was believed to be a contaminant and the evidence was discarded. As a result, not until craniotomy had been done was the correct pathologic process determined. Case 2 was that of torulosis in a patient with diabetes mellitus and lymphatic leukemia. The diagnosis was made by the unsuspected finding of yeastlike budding organisms, on microscopic examination, in the spinal fluid. These were identified by further laboratory procedures as Torula histolytica. In the third case the torula infection (the organism was isolated in the spinal fluid) of the central nervous system was of one year's duration. The patient is still doing her daily housework with little inconvenience from the infection. The average length (Levine) of the disease is five or six months. The longest case on record is that of a patient who lived five and one half years. The total of such cases now reported in the literature is sixty-six. Torula infestation of the central nervous system may resemble tuberculous meningitis, encephalitis, cerebral tumor and sometimes abscess of the brain, dementia psychosis and dementia paralytica.

Quantitative Study of Zinc in Nutrition.—Scoular performed thirty-five zinc balance studies, for which she used three normal boys of preschool age. The ashed food, feces, urine, distilled water and acid alcohol were analyzed spectrographically for zinc by comparing their spectrums with those produced by solutions of known concentration. The zinc values for food which were analyzed by quantitative spectrographic technic were found to be almost 40 per cent lower than the theoretical values estimated from published analyses for which the turbidimetric method has been used. From 0.04 to 6 per cent of the ingested zinc was eliminated through the urine. The rest of the excreted zinc, representing from 42 to 164 per cent of the ingested amount, was eliminated through the alimentary tract. Since more than two thirds of the thirty-five balance studies gave retentions which were significantly greater than the error determined for the method used, it would seem that zinc is associated with physiologic functioning. On the basis of the limited ingestion range studied it is tentatively concluded that 0.307 mg. of zinc per kilogram of body weight will supply the zinc needs of the preschool child.

Chronic Oral Administration of Atabrine.—Since daily medication is the rule in malarial prophylaxis, Martin and his colleagues made an attempt to determine the survival period, symptomatology, and the gross and microscopic changes in healthy rabbits, cats and dogs following repeated daily oral feeding of from 17 to 80 per cent of the minimal lethal dose of atabrine. These doses caused death in from nineteen to three days, respectively. The effects of such medication were chiefly gastrointestinal intolerance, disturbances of the central nervous system, progressively increased weight loss associated with anorexia and body weakness, and a yellowish discoloration of the skin, sclera and mucosa of the gastrointestinal tract. Animals receiving from 2 to 3 per cent of their oral minimal lethal dose of atabrine remained in good condition for from six to seven weeks and showed no symptoms except a slight loss in body weight. Gross and microscopic studies of animals examined post mortem revealed certain pathologic changes, but none were specifically characteristic of atabrine toxicity.

Thoracoplasty Brace. J. D. Steele Jr., Milwaukee.—p. 342.

Recovery Following Gangrene of Lung.—Berg and Dieffenbach state that acute pulmonary gangrene developed in a patient with a subclavicular cavity of several months' duration. This cavity was diagnosed tuberculous by the presence of certain symptoms and the absence of others, and by the presence of acid-fast organisms in the sputum on several occasions. The gan-

grene that developed consequently was extensive enough to involve the tuberculous area in its entirety. Complete recovery followed surgical drainage and thoracoplasty. This case differs from all other reported cases of the two conditions occurring simultaneously only in its favorable outcome. It is reported for the purpose of calling attention to the fact that if gangrene develops in other patients with tuberculous lesions accompanied by a low Gaffky sputum count the prognosis need not be considered hopeless. Modern surgical intervention permits some expectation of complete recovery

Nephrobronchial Fistula.—Fistula secondary to inflammatory processes in and about the kidney may occur at any point adjacent to the renal area, but bronchial fistula is apparently rare Lee points out that bronchial fistula should be suspected in those cases in which the patient gives a history suggesting a pathologic process in the kidney or perinephric abscess, accompanied or followed by pulmonary symptoms, severe cough and profuse sputum Some degree of pulmonary involvement probably accompanies many perinephric abscesses, but the sudden onset of severe cough and profuse purulent sputum is a particularly significant symptom of bronchial involvement. Additional evidence suggesting perinephric abscess is rales or dulness in the overlying base of the lung and elevation of the diaphragm with an overlying inflammatory process in the lung. Drainage of the perinephric abscess usually results in immediate and marked relief of the cough and sputum, with a more gradual but usually complete clearing up of the pulmonary involvement. When the kidney is markedly involved, nephrectomy may be necessary later.

Precocious Hypertrophy of Prostate.—Powell reports a case of hypertrophy of the prostate in a boy of 17 years following treatment of undescended testes with gonadotropic substance. The return of the prostate to the near normal condition after treatment was discontinued in this case offers further proof of the causal relationship between the proved hypertrophy and the glandular therapy. The author warns that caution should be exercised by the physician in treating a young man past puberty with gonadotropic substance. It is his opinion that any patient receiving such treatment should be watched carefully and that treatment should be discontinued on the occurrence of the first symptoms indicating an abnormal stimulation of the secondary sex organs.

Chaulmoogra Oil in Arthritis.—Stanley presents the results that he obtained with chaulmoogra oil in the treatment of fifty patients suffering from the atrophic, hypertrophic or mixed forms of arthritis. He acknowledges that the treatment is purely empirical but states that much relief of symptoms ensues. As a rule, the highest percentages of improvement were attained in the acute and subacute forms of the disease. The more general classification of cases was used. Two major hypotheses are proposed in an endeavor to account for the efficacy of chaulmoogra oil in arthritis: (1) its bactericidal potency and (2) its influence on the retention of calcium While the use of chaulmoogra oil in arthritis is empirical, the uniformly favorable experience which has attended its employment by the author and others appears to warrant its continued trial as a therapeutic agent.

Fever of Undetermined Etiology.—Smith presents a review of patients discharged from the University Hospital during the last ten years in whom the final diagnosis was fever of unexplained etiology. Patients with fever of less than one month, those whose fever subsided during observation although not diagnosed, postoperative cases with fever and children less than 14 years of age were excluded from the study. After these restrictions were adhered to there remained seventy-five cases. Satisfactory follow-up information was obtained in fifty-one cases, some by reexamination, some by information from the local physician and some by questionnaire. Fever of unexplained origin occurred in four classes of patients: (1) those with acute or subacute infection, type and location not determined (thir-

teen), (2) those with neoplasms, origin not apparent (nine), (3) those with rheumatic infections (seven) and (4) those whose fever may possibly be psychogenic in origin (twenty-two) In the first group of cases fever of more than 101 F, leukocytosis or secondary anemia in the majority of them and an elevated sedimentation rate were found These cases defy diagnosis, yet the diagnosis of sepsis would seem to be in order The erythrocyte sedimentation rate has been found to be a rather accurate index of tissue destruction either in neoplasm (second group) or in infection In the third group of cases one year elapsed before a diagnosis of arthritis was made The probability is suggested that the rheumatic state was the cause of the fever from the beginning Rheumatic heart disease occurs in many people who have never had arthritis Also many persons with clinical rheumatic fever recover and evidence of a valve lesion never develops in them However, it seems certain that some patients with undiagnosed fever in whom arthritis or a valve lesion never develops have rheumatic infection, how many must remain a matter of speculation until the etiology of rheumatic infection is positively determined and laboratory diagnosis in the active stage becomes possible In the twenty-two cases of the fourth group there was no objective evidence of a pathologic condition at the time of observation and none has subsequently developed over periods varying from one to ten years In this group every apparently indicated study was carried out with the exception of the brucellin cutaneous test and the sedimentation rate, which was not done in some earlier cases Most of the patients in this group were seen by a psychiatrist, who diagnosed psychoneurosis in the majority of them Fever continued in all except one case In this case the comparatively short period of fever before and after observation, five months and two months respectively, suggests the probability of an organic cause, of which the sedimentation rate might have given evidence The duration of fever before the author's observation in these cases (average 3 8 years) and its length in the follow-up (average three years) would seem to be sufficient time for any organic cause to become evident or for fever due to most causes to subside The author is inclined to agree with those who believe that fever can be of psychogenic origin and to classify these cases under this diagnosis The recognition of psychogenic fever is exceedingly difficult and such a diagnosis should be considered only after a prolonged and thorough period of observation The sedimentation rate is a valuable diagnostic procedure in differentiating infectious fevers from questionable psychogenic ones

Distribution of Sulfanilamide in Tissues.—Engelfried states that free and conjugated sulfanilamide may be recovered from all organs, tissues and fluids of the rabbit, guinea pig and man There is a high percentage of conjugated sulfanilamide in the liver of normal rabbits This percentage found in blood and various tissues of the animals varies with the individual animal Sulfanilamide is eliminated from the body in the urine as free and conjugated sulfanilamide However, a small percentage may be excreted in the stool The complete elimination of the drug from the body will require several days, depending on the amount of drug stored in the tissue and the daily urinary output The quantity of sulfanilamide recovered from the tissues and fluids of two normal adult rabbits four hours after the intraperitoneal injection of the drug was 78 and 81 2 per cent Under the same conditions, 88 5 and 96 4 per cent was recovered from two normal adult guinea pigs

Hyperhidrosis of Nervous Origin and Sympathectomy.—White believes that sympathetic denervation of the arm and leg offers a safe and certain cure for hyperhidrosis The operation results in warm and dry extremities If care is taken to avoid the ocular fibers (the section of which results in Horner's syndrome) and to leave the highest portion of the lumbar chain in the male intact (in order to preserve the power of ejaculation) there are no annoying sequelae Case histories are presented Hyperhidrosis in the hands was relieved in one case by paravertebral infiltration of alcohol round the first and second thoracic ganglions, with only a single night's hospitalization and without any interruption of the patient's employment A second equally successful result has been obtained by Freeman Nevertheless it is the author's belief that with rare exception surgical denervation is the better procedure, as its action is certain and the operative risk is almost nil in young and otherwise healthy individuals After alcohol block there is considerable risk of incomplete results and some risk of producing a troublesome intercostal neuritis The procedure must usually be carried out bilaterally, when it is safest to do the operation in two stages The second operation can be done from four days to a week after the first, so that the total period of hospitalization is generally less than two weeks when both arms are denervated, and less than three weeks if both lumbar chains are resected

Treatment of Dermatophytosis.—A number of authors have reported high percentages of good results or "cures" with the various types of fungus extracts while a minority have found such preparations practically valueless Traub and Tolmach question the advisability of using the term "cure" because only prolonged observation and repeated microscopic and cultural studies could determine this point They believe that only those experiments can be accepted in which the authors actually proved that they were dealing with cases of dermatophytosis "Mycotic-like" eruptions with a positive trichophytin test, cases of probable "ids" and eczematous hand and foot eruptions clinically called dermatophytosis and dermatophytid are not the carefully selected type of cases on which such a study should be based It is difficult to evaluate accurately the results of therapy in dermatophytosis, which even if left untreated runs a most capricious course of improvement, apparent cure and relapse Therefore the authors believe it doubly difficult to judge the value of the biologic remedies when local measures in addition to the injections of vaccines are used Regardless of the type of vaccine or the type of case, the number of patients entirely uninfluenced by treatment remains high and

approximately the same and the number cured or improved relatively low. The longer that the authors followed their patients, the smaller grew the number of cases that they were able to report as "cured" or "improved." They do not feel that vaccine, trichophytin or convalescent serum treatment of dermatophytosis should be discarded but rather that stock of these agents should be taken. The biologic methods of treatment still belong in the laboratory and should not yet be advocated for general use. Some good results in a small number of cases have been reported, but the reasons for the small percentage of good results regardless of the methods of biologic treatment should be investigated. Perhaps the soil on which the fungi grow is altered by factors which have not been taken into account and which, if understood, might help in controlling the disease. Certainly the general health of the patient is a factor. In one instance a long standing proved case of dermatophytosis was completely cleared up following a thyroidectomy. The patient has been observed for seven years since operation and the eruption has not recurred. Methods of preparation of the vaccines and extracts and the question of dosages must be further studied and considered. At the present time it is the authors' belief that the usual local remedies, Whitfield's ointment, x-rays, boric acid ointment, wet dressings with boric acid, Burow's solution or potassium permanganate and the like are still the most practical and useful agents at hand. The routine use of fungus extracts and vaccines by the dermatologist and general practitioner is not yet justified by the results obtained. Further work must be done in this field and this should be considered experimental only.

Sulfanilamide for Chancroid. — Kornblith and his co-workers used sulfanilamide in the treatment of ten cases of chancroid. For the first five days the patient was given daily 80 grains (5.2 Gm.) of the drug, 20 grains (1.3 Gm.) after each meal and before bedtime. From the sixth to the fifteenth day, inclusive, 40 grains (2.6 Gm.) was administered daily, 10 grains (0.65 Gm.) after each meal and before bedtime. After this period, treatment was stopped whether or not the lesion was healed. The entire treatment was ambulatory. There were no untoward effects. The patients were cautioned to stop the drug if diarrhea developed and not to use a saline cathartic in case of constipation. They were instructed not to drink more than 1 quart (liter) of fluid during any twenty-four hours. The only other treatment advised was the use of soap and water to cleanse the lesion locally twice a day. The average time for healing was about two weeks. The authors state that, since the foregoing was submitted for publication, sixty-five proved cases of chancroid have been treated with sulfanilamide and followed. The results have been uniformly excellent. There has been no failure or recurrence. All the lesions were healed after two weeks of treatment with sulfanilamide alone.

Dual Etiology of Intractable Asthma.—Balyeat and Seyler believe that more than 90 per cent of all cases of intractable asthma have a dual etiology: (1) sensitization factors (food, animal emanation and various dusts, pollen and miscellaneous) and (2) mechanical factors (mucus plugs, purulent bronchial secretions, asthmatic bronchiectasis and the usual form of bronchiectasis). Their recent work leads them to believe that the mechanical group of factors is of equal importance in the majority of cases and, in many, of greater importance than the sensitization factors. Practically all cases of intractable asthma start with periodic attacks of asthma due to local edema of the mucosa of the bronchial tubes, produced by contact with some substance to which the patient is specifically sensitive. Later a superimposed infection occurs in these patients, which leads to the production of mucus or purulent material. The plugging of the bronchial tubes with mucus or purulent exudate mechanically produces attacks of asthma. Why asthmatic attacks in cases of intractable asthma occur about the same time each night is explained by the authors by the fact that the amount and rate at which mucus is secreted determine when the bronchial tubes are filled and nature requires them to be cleaned out—the asthmatic attack. In many cases of asthma it is difficult to determine what actually causes death. During the last two years the authors made bronchograms in about 200 cases of intractable asthma, and they find that the majority of patients suffer from some type of bronchiectasis. Most of these patients had leukocyte counts of from 12,000 to 18,000, which is evidence of toxin absorption. They believe, therefore, that death in the majority of cases of intractable asthma is due to chronic sepsis.

Lipoid Pneumonia in Infancy and Childhood.—Broadly speaking, Wolman believes that lipoid pneumonia is preventable and that it could be eliminated if the facts concerning its etiology were known to all who share in the care of infants and children. Although individuals of any age may be affected, the disease is encountered more frequently at both extremes of life. Infants, and especially debilitated infants, seem to be particularly susceptible. The growing use of oily preparations, both as a source of vitamins and in the treatment of respiratory and gastrointestinal diseases, contributes to its increasing frequency. Infants should be fed cod liver oil only when awake and while held in a semierect or sitting position. Oily nose drops in the first two years of life are potentially dangerous; aqueous solutions for intranasal medication are preferable. Parents and nurses should be warned against the forcing of cod liver oil or other oils when the youngster refuses and resists. The blocking of a child's nostrils in order to make him swallow must be absolutely forbidden. Newborn or premature infants and all babies who vomit should be given vitamin concentrates rather than the larger doses of crude cod liver oil. In the feeding of oils and similar substances to weak or debilitated patients, especially to neurologic patients, the greatest forethought and precautionary care should be exercised; that is, aspiration should be prevented at any cost.

Concentration of Glutathione in the Erythrocytes of Patients with Rheumatic Fever. M. P. Schultz.—p. 264.

Formol-Gel Reaction and Carditis.—Schultz and Rose studied the serums of 108 febrile hospital or convalescent home patients afflicted with various diseases and seventy with rheumatic fever. The occurrence of both gelation and opacity were observed and recorded. When all the observations (or all in which the erythrocyte sedimentation rate was more than 9 mm.

an hour) in each group are compared, it is evident that positive formol-gel reactions were more frequently observed in rheumatic fever serums than in control serums, although the severity of the illness as reflected by an increase in the erythrocyte sedimentation rate was comparable in the two groups. This is due to the occurrence of more positive formol-gel reactions at relatively low erythrocyte sedimentation rates in the rheumatic fever patients. In the control patients ill with various febrile diseases, the formol-gel reaction was positive only in cases of severe illness. In these instances a parallel was demonstrable between the degree of erythrocyte sedimentation rate acceleration and the occurrence of positive reactions. The results in adult rheumatic fever patients severely ill with arthritis were similar. Patients with rheumatic carditis, on the other hand, reacted differently: (1) strongly positive formol-gel reactions were observed in individuals without obvious severe illness, with relatively little fever and with but slightly increased erythrocyte sedimentation rates, and (2) during the course of illness the occurrence of positive formol-gel reactions did not parallel that of most rapid erythrocyte sedimentation rates. In cases of rheumatic carditis the formol-gel reaction frequently became positive as the erythrocyte sedimentation rate was declining but coincident with the development of signs of active carditis. In some instances the test remained strongly positive while the erythrocyte sedimentation rate returned to normal. A strongly positive result in children, or in adults in the absence of arthritis, is suggestive of active carditis even in the presence of a relatively slow erythrocyte sedimentation rate. Persistently negative reactions indicate that severe carditis is probably not present and may be considered of favorable prognostic import. These observations suggest that the formol-gel reaction may be a valuable additional aid in determining the presence of active rheumatic carditis in patients known to be suffering from rheumatic fever. In those occasional instances in which positive formol-gel reactions persist longer than elevations in the erythrocyte sedimentation rate, this test may provide the only evidence of continued rheumatic activity warranting continued limitation of physical activity. The formol-gel reaction is apparently not influenced, as is the erythrocyte sedimentation rate, by the presence of cardiac decompensation or anemia.

Surgery for Ulcerative Colitis.—Rankin states that medical management of chronic ulcerative colitis, which consists of a dietary regimen, administration of vitamin C, elimination of focal infections and the use of vaccines and serum, is effective to some degree in the majority of cases. The principal indication for surgery is intractability to medical treatment with resulting damage to the colon, following which the function of the colon is lost and under which conditions it becomes filled with pus and detritus and is a source of absorption. Therefore surgery for chronic ulcerative colitis as for duodenal ulcer is indicated only for the complications, which occur in 15 per cent of the cases. These complications call for various types of surgical intervention. Surgery in the acute, fulminating or hemorrhagic forms of ulcerative colitis has few, if any, advantages. In this type of condition, ileostomy which completely by-passes the fecal current may be done under local anesthesia and occasionally appears to accomplish something. Total or subtotal colectomy should be carried out in multiple stages. Multiple stage operations increase the margin of safety. Sufficient time after an ileostomy should be allowed to elapse before resection is undertaken, in order to replace fluid loss, balance the blood chemistry and increase body weight and strength. The removal of a part or all of the large intestine for chronic ulcerative colitis is definitely desirable when the colon has lost its function.

Medical Treatment of Bronchiectasis.—In the diagnosis of the various types of bronchiectasis, infinite care must be exercised to arrive at definite conclusions. Fortunately, Singer declares that x-ray studies, expert laboratory facilities and the increased acumen in physical diagnosis have made it possible to sift out properly the bronchiectasis from the many pulmonary cases which formerly were diagnosed as tuberculosis, abscess of the lung or even as malignant conditions. Probably the greatest strides thus far have been in finding suitable cases for surgical approach. It has taken almost twenty years to have a fairly good idea of bronchiectasis, and in the next few years a cure may even be found. The careful study of the bacteriologic flora has contributed much to the knowledge of bronchiectasis. The treatment of sinus infections along with other symptomatic treatments have been helpful. The use of postural drainage has kept many patients so well drained of their purulent secretions that complications have been kept down to the minimum. The use of compression belts to support the abdominal muscles and also to raise the diaphragm has been effective in reducing discomforts of coughing and also aiding in expectoration. Medical treatment, while not always effective, has often improved the patient sufficiently for surgical treatment to be undertaken.

Results of Repeated Operations on Stomach.—Finsterer gives the results in a series of 331 cases in which repeated operations (2,753) were performed. There was a total mortality of 11.7 per cent, but it dropped to 8.6 per cent if cases complicated by acute perforation, acute hemorrhage or gastrocolic fistula are omitted. The most frequently performed previous operation was gastro-enterostomy, 190 cases, after which either the old ulcer had not healed or a gastrojejunal ulcer had formed. The radical operation for a gastrojejunal ulcer, following posterior gastro-enterostomy, shows a lower mortality, 6.8 per cent, than when it follows resection, 23.5 per cent. Therefore an operation is indicated at once by the return of complaints in a patient after gastro-enterostomy; and it is to be delayed if the complaints return after resection until at least several attempts with medical therapy have been made. The mortality rate attending the radical operation for recurrent gastrojejunal ulcer is 21.4 per cent. In acute perforation even the lesser operation, either closure or excision of the ulcer, produces poor results. Radical operation for gastrojejunal ulcer under general anesthesia showed a mortality rate of 42.1 per cent, nineteen cases with eight deaths. Three of these deaths were directly attributable to the anesthetic. With local anesthesia the mortality rate was 14.1 per cent. The best permanent results are achieved with the extensive two-thirds to three-fourths resection of the stomach and the preparation of the end to side anastomosis according to Hofmeister-Finsterer, even though there may have been several preceding operations. Of ninety-six patients, eighty-eight are permanently cured, or 91.6 per cent. The author states that the recurrence of a gastrojejunal ulcer after radical operation is not due to special ulcer disposition but to technical faults, too limited resection, Y shaped anastomosis or entero-anastomosis. Therefore, by avoiding these errors in technic, permanent cure is possible even after repeated resections. The term "surgically incurable ulcer" is not applicable to this type of case. The disadvantages of extensive gastric resection, too small a stomach and anemia are of little consequence since they are more easily controlled than a gastrojejunal ulcer following inadequate gastric resection.

Cellulitis of the Colon.—Obstruction from inflammatory reaction and swelling of a length of colon, occurring at the time of the acute inflammation, is the only type of intestinal obstruction that Hailes has encountered in diverticulitis. He refers to true obstruction and not to impaired function of the sigmoid colon. This swelling is much more extensive than that usually seen in the cecum in association with acute appendicitis in those cases in which the cecal wall is involved, a statement which applies both to the induration of the intestinal wall and to the length of intestine involved. The acutely inflamed sigmoid colon appears quite often to be the origin of the inflammatory exudate and not the diverticula. A large area of visceral peritoneum is inflamed. Because of the association of the swelling of the intestine with acute inflammation in one or more diverticula in these cases, it can be assumed that the inflamed diverticulum is responsible for the cellulitis and this cellulitis may be the most prominent lesion present. The cellulitis may be localized to one portion of the sigmoid colon or involve the whole sigmoid or even the whole of the descending colon. The degree of swelling of the intestine may be extreme and it is not uncommon to see a sigmoid loop so swollen and indurated that the loop in question is unmanageable surgically if obstruction has supervened. Cellulitis of the intestine pursues the same course as cellulitis elsewhere in the body and may lead to resolution, local abscess formation, with or without rupture, or obstruction. The presence of diverticula merely indicates the possibility of diverticulitis. A long filling defect, associated with a short history, inflammatory signs and the presence of diverticula, is significant but affords no more than a ray of hope that the condition may not be malignant. The author's experience is that the more extensive the cellulitic reaction, the more likely is the condition to be inflammatory and not malignant.

Epidemic Nausea and Vomiting.—Toward the end of 1938 an outbreak of nausea and vomiting occurred in South Hampshire. Gray describes this epidemic in order to show that the Thanet outbreak reported by Miller and Raven in 1936 was not an isolated incident and to suggest the probability of the widespread incidence of the disease. In general the illness is short, lasting about two days. The patient complains of dizziness, nausea and vomiting. Less frequently, dizziness and nausea alone may occur. It is usually afebrile. In the South Hampshire epidemic, frontal headache and occasionally bradycardia were also noted. In common with the Danish outbreak (1935) diarrhea was encountered in the epidemic reported by the author and a higher incidence of mild pyrexia was seen as compared with that in Thanet. The epidemic occurred in an institution and the surrounding country at the same time, the total number of patients being twenty-six: thirteen women, six men and seven children. The first case was seen September 26 and the last October 31. Nineteen patients complained of giddiness, twenty-four vomited and all had nausea. Diarrhea was complained of by eleven, three had slight elevation of temperature, three had frontal headache and three had abdominal tenderness. As the disease is of such short duration it is difficult to decide what particular system is attacked. Earlier papers suggest either the gastrointestinal or the nervous system. So far, in all examinations made no organisms known to cause gastro-enteritis have been found. The greatest argument against a food or water contamination is the type of spread in families. Instead of the whole community going down at once there is a gradual peripheral spread. In the school cases two children went home and two days later both parents contracted the disease. In cases 15 to 20 of the country epidemic the passage from one individual to others in the family is clearly seen. Evidence would suggest that it is a person-to-person infection with an incubation period of at least two days. As Miller and Raven suggest, the probabilities point more to an acute infection of the central nervous system, possibly of a virus type. All the symptoms except the diarrhea may then be explained. Presumably a droplet infection is the mode of spread. It is difficult to assume that the attacks heretofore reported are isolated incidents; more probably sporadic cases occur about the country and flare to epidemic proportions only when the environment is ripe. The importance of this disease does not lie in its manifestations, which are mild, but in the possibility of its being confused with an outbreak of food poisoning or Sonne dysentery when it occurs in institutions. The latter are more serious matters than epidemic nausea and vomiting.

Sporadic Cases of Typhoid.—Hay gives an account of ten nonepidemic cases of typhoid seen during the last four years in two relatively small areas (population approximately 45,000 each). He believes that his report illustrates the protean nature of the disease with regard to its clinical manifestation, infectivity and transmission. In only two instances was typhoid suspected during the initial stages of the disease. The author states that his ten cases of sporadic typhoid illustrate (1) the difficulty in establishing a correct and early diagnosis on clinical grounds alone, (2) the importance of obtaining a specimen of blood for examination in any obscure case of fever or indefinite illness, (3) the apparent variation in susceptibility of individuals to infection, (4) the fact that transmission of the disease may occur in so many ways that each case presents an individual problem and (5) the value of close cooperation between the medical practitioner and the medical officer of health.

*Narcosis Therapy: Critical Review. R. D. Gillespie.—p. 45.

Narcosis Therapy.—In his critical review of the value of therapeutic narcosis, Gillespie states that continuous narcosis if thoroughly carried out is still fraught with some danger in spite of modifications in treatment. Freedom from risk is proportionate to the experience and care of those undertaking the treatment. The recovery rate in continuous narcosis in recent

psychoses never exceeds and usually falls short of the ultimate spontaneous recovery rate. Its therapeutic value is therefore confined mainly to curtailing the duration of psychotic conditions which would eventually pass spontaneously. It is most successful in manic excitements and considerably less successful with depressions of the manic depressive type. With recent schizophrenic disorders its effects are best in excited schizophrenia of the agitated fearful type and in hebephrenia in which the onset has been acute. Psychogenic schizophrenic disturbances in schizoid psychopaths are particularly amenable to this method. Little success is obtained with paranoid schizophrenia and with catatonic stupor. In general, when a psychotic illness follows a relapsing, recurring or periodic course with an acute onset and exogenic causes the more likely is continuous narcosis to curtail the episode. These are essentially the more spontaneously recoverable types. Continuous narcosis also has an administrative value in making chronic psychotic excitements more manageable. Occasional unexpected social recoveries are produced in chronic depressive (affective) psychoses and in chronic schizophrenia. Recently two authors obtained an unprecedentedly high recovery and discharge rate in a small group of schizophrenic patients in whom the duration of the illness was more than two years. The treatment is still entirely empirical and its efficacy is difficult to estimate because different investigators employ varying diagnostic criteria.

*Transfusion with Placental Blood. J. Halbrecht.—p. 202.
Diverticula of the Duodenojejunal Flexure. R. W. Raven.—p. 203.

Serum and Sulfanilamide in Infections.—Loewenthal states that a single dose of sulfanilamide administered at the time of infection with hemolytic streptococci will protect only a minority of normal mice, whereas it protects the majority of animals which have received, from sixteen to eighteen hours before infection, a dose of antiserum which by itself is incapable of preventing death. Mice infected with hemolytic streptococci can be effectively treated with a combination of sulfanilamide and antiserum even if this treatment is given as late as eighteen hours after infection, when the animals are already severely ill. Since neither sulfanilamide nor antiserum alone achieves this result, it appears that these two agents act in a different but complementary manner.

Placental Blood for Transfusion.—Page and his associates have given twenty-five transfusions of stored placental blood and have had only one severe reaction. This did not appear to have been due to the placental blood but to the development of iso-agglutinins to the cells of the original donor, the patient's son. Slight rises of temperature have occurred on other occasions early in the series and have appeared to follow undue heating of the blood. The authors are now of the opinion that it is unnecessary to heat the blood to body temperature before use. Placental blood is preferable to ordinary adult blood because it contains no food allergens and because its clotting power is greater. The latter is an advantage in dealing with hemorrhage. A citrate saline solution has been found to be the best anticoagulant, for it gives minimal hemolysis after prolonged standing. Sterile collection of the blood is imperative if contamination is to be avoided. The authors find that the third stage of labor is not prolonged when placental blood is collected. There was no appreciable difference in the blood counts of twelve babies whose placentas had supplied blood and twelve controls, performed on the first, second and seventh days after birth and immediately before discharge from the hospital on about the fourteenth day. Icterus occurred in mild degree in three cases, one in the placental group and two in the control group.

Transfusion with Placental Blood in Malaria Countries.—Halbrecht points out that the use of preserved blood, especially placental, has an added advantage over fresh blood in countries with endemic malaria. To be absolutely safe one must not inject fresh blood from any one who has at any time had malaria, whereas with placental blood, even if the mother has had malaria recently, the organisms usually do not pass the placental filter. Still more important is the fact that in preserved blood the plasmodium dies quickly. Preserved placental blood is thus doubly safeguarded. Up to now 116 transfusions of placental blood obtained from 520 placentas have been given. There were no serious accidents and only four reactions, three consisting of a chill and one of dyspnea and tachycardia. The author urges the greater exploitation of this source of blood and states that the need of blood for transfusions in Palestine is great, owing to the large number of casualties admitted.

A Trip Abroad, 1937-1938. J. E. Sherwood.—p. 112.

Types of Scarlet Fever in Sydney.—During a mild epidemic of scarlet fever in Sydney during the winter of 1936, White and his co-workers isolated and typed the infecting strains of hemolytic streptococci from 314 patients. The serologic classification of Griffith was used and the prevalent epidemic strain was found to be type XVII. A similar survey was carried out in the late summer, autumn and winter of 1938. During this period there was no epidemic prevalence of scarlet fever. No one serologic type predominated among the 307 patients. Type XI was found throughout the whole period, but its incidence remained at a fairly steady level. The distribution of Griffith's types causing scarlet fever in Sydney is different from the distribution found in England. In England, types I, II, III and IV account for from 60 to 70 per cent of scarlet fever; in Sydney, 75 per cent of the scarlet fever was caused by types I, IV, XI and XVII in the period under review. A comparison of the capsulated and noncapsulated strains suggests that the capsulated strains have a greater tendency to spread in a community. The capsulated strains are much more likely to give rise to familial infections than the noncapsulated strains. Cross infection was the rule rather than the exception. This confirms similar work in English hospitals.

Tuberculosis in Cyprus (Final Report). N. D. Bardswell.—p. 165.

Treatment of Cervical Adenitis.—Hunter used a medium made up of 0.85 Gm. of sodium chloride, 5 Gm. of calcium chloride, 5 Gm. of gelatin, 0.05 Gm. of acriflavine and enough distilled water to make 100 cc., in the treatment of twenty-one children with tuberculous cervical adenitis from 20 to 35 mm. in diameter. The medium was injected into the abscessed gland. From 0.3 to 0.5 cc. of the solution was used for every daily injection. The abscess regressed in twenty cases. Bilateral involvement was found in a few cases, and they responded satisfactorily to treatment. Scarring occurred in only three cases, in two of which they are difficult to detect. Twenty-nine children with slight adenitis with glands less than 20 mm. in diameter, and possibly tuberculous, received an average of three injections each of solution. A favorable response was obtained in twenty-eight. This method appeared to inhibit further hyperplasia; it holds out great promise in the prevention or treatment of cervical adenitis. After the medium has been injected at about six sites and provided the gland ceases to enlarge and soften, the injections can be discontinued until no further reduction in size takes place for a fortnight before more injections are given.

Is Silicosis a Disease Entity? A. Langelez.—p. 563.
*Importance of Facial Paralysis in Localization of Cerebral Tumors. Y. Piette.—p. 572.

Facial Paralysis in Localization of Cerebral Tumors.—Piette maintains that facial paralysis is observed frequently in the evolution of cerebral tumors. In the examination of thirty cases presenting the syndrome of intracranial hypertension it was observed twenty-one times. In one case it was due to a chronic subdural hematoma and in three cases an arachnoiditis existed. In the other cases there existed tumors of the cerebral hemispheres or of the posterior fossa. Facial paralysis was accompanied by homolateral pyramidal signs in five cases (frontoparietal tumor, tumor of the thalamus, craniopharyngioma, rolandic tumor and tumor of the fourth ventricle). The facial paralysis was of the peripheral type in only four of the cases; the cases in question were acoustic neurinoma, arachnoiditis of the posterior fossa, tumor of the fourth ventricle and a meningioma adhering to the tentorium cerebelli, passing between the cerebellar tentorium and the cerebral peduncles and then passing under the tentorium into the posterior fossa. This tumor was accompanied by homonymous, left-sided hemianopia and the syndrome of the right cerebellopontile angle. Facial paralysis of the peripheral type is an important symptom of tumors of the acoustic nerve and of the cerebellopontile angle. Facial paralysis of the central type is frequently encountered in cerebral tumors of various locations. When the paralysis is an isolated symptom it permits only the determination of the side of the location of the tumor. On the other hand, it assumes great importance if it is accompanied by early psychic disturbances or by motor aphasia. In these cases it indicates almost with certainty a tumor of the frontal lobe.

Ovariectomy During Gestation.—Portes and Varangot maintain that the majority of surgeons, believing that the early exeresis of ovarian cysts avoids the complications due to their rapid growth, their suppuration and especially their torsion, think that "all cysts of the ovary that are diagnosed must be subjected to surgery." This essentially prophylactic conception, and from this point defensible, seems nevertheless in need of revision on the basis of the present biologic knowledge. Ablation of ovarian cysts is not always indicated because some of them, the follicular cysts for example, must be considered as "functional" cysts, abnormal to be sure but likely to disappear spontaneously after the biologic disorder which has given rise to them has subsided. In the course of gestation the prophylactic attitude which favors the ablation of the ovarian cysts appears to have greater justification by reason of the extreme frequency of torsion, which may develop unexpectedly either in the course of gestation or immediately after delivery. However, there are contraindications to surgical intervention; on the one hand, it must be considered that many of the cysts are purely functional; the lutein cysts, for instance, are relatively frequent in the course of gestation; on the other hand, the effects of ovariectomy on the development of the frequency are uncertain. On the basis of experiments on animals and of clinical observations, the authors have been led to accept the following points with regard to ovariectomy in the course of gestation: 1. Ovarian cysts that are diagnosed during pregnancy do not necessarily have to be subjected to surgical treatment or, in an emergency, they have to be so treated only as late as possible. 2. It is wise to remove them only when this is necessary on account of mechanical or infectious complications (torsion, hemorrhage and suppuration). 3. Even in cases in which the intervention is formally indicated, it is advisable to respect the corpus luteum as much as possible, which is easy when it is localized in the healthy ovary, but it is also often possible by dissection or partial resection of the cystic pockets, when it is localized in the diseased ovary. 4. Finally, in the cases in which the ablation of the corpus luteum is inevitable, it is advisable to substitute for it, after the operation, by injecting daily and for a long period massive doses of progesterone without counting too much on the secretory action of the placenta. The authors consider this attitude as the one which, at least in principle, respects the pregnancy as much as possible when it is associated with the development of ovarian cysts.

Accidents in Skiing.—Having discussed the incidence and the etiology of skiing accidents in a previous report, in this paper Braine and Goury take up the lesions as such. The lesions of the inferior members are most frequent and most characteristic in skiing. The typical lesions result first of all from torsional movements, conditioned by the close connection of the foot with the ski. Soon they are restricted to the region of the ankle, the most vulnerable site in the skier; soon the torsion is transmitted to the knee. Moreover, the lesions may be in the hip or in the trochanteric region. The sprains of the ankle joint injure chiefly the external lateral ligament, the anterior talofibular fasciculus of which is typically broken by forced adduction. Following further discussion of benign and grave sprains of the ankle joint, the author takes up the typical skiing injuries of the knee joint. The majority of them, not being grave, escape medical control, for many skiers content themselves with bandaging their own injured knee. As a rule it is the tibial collateral ligament which is injured. Other lesions of the knee that are encountered in skiers are ruptures of the cruciate ligaments and partial fractures by tearing away of the tibial spine, the edge of the tibial plate and so on. Lesions of the menisci, although often suspected, are rarely confirmed. The fractures of the leg that are typical for skiing are the spiral fractures. The tibial lesions are usually located below the middle of the leg. The point of the upper fragment often menaces the skin. The fibula is usually fractured higher up than the tibia. Nevertheless, although it happens rarely, the two bones of the leg may be fractured simultaneously and at the same level. Fractures of the thigh result often from direct contact with an obstacle. However, spiral fractures by torsion are also observed in the thigh. They are often in three fragments and are localized either in the upper third (subtrochanteric) or in the median third of the diaphysis. Fractures of the neck of the femur are rare in skiers, but trochanteric fractures are characteristic, particularly in skiers with insufficient training. Sprains of the hip joint and ruptures of the pelvitrochanteric muscles may give rise to deep pericoxal hematomas. Among the lesions of the superior members the dislocation of the shoulder takes the first rank. The role of the skiing sticks seems to have been exaggerated in the etiology of this lesion. It appears that a certain position of the arms favors this lesion. The traumas of the hand of the skier have two classic locations: they are metacarpophalangeal sprains of the thumb and metacarpal fractures. In these lesions the skiing sticks do play an essential etiologic part. Other lesions of the superior members which occur in skiing are those of the wrist, the forearm, the elbow and the humerus. Excoriations, particularly of the face, may result in unsightly scars. Although cranial fractures are rare, commotio cerebri and lesion of the eye are of considerable importance. Some of the ocular lesions

lead to loss of vision. Traumas of the vertebral column involve chiefly the cervical portion. The thoracic lesions are as a rule more or less severe contusions. Traumas of the abdomen may cause visceral lesions. After pointing out that adequate training of the skier will prevent many accidents, the authors stress the importance of suitable first aid. Transportation of the injured has been organized and improved by the efforts of an international association. Discussing transportation, the authors stress the advantages of Pourchier's ski-sleigh, a sort of stretcher-sleigh combination which can be constructed with the aid of the skiing equipment, the skis serving as runners and the sticks as framework of the stretcher; illustrations clarify the construction. The treatment of sprains has been greatly improved since the use of Leriche's method (local injection of anesthetics) has become widely known. Many skiers now carry syringes and ampules with them. The reduction and immobilization of fractures must be accomplished as early as possible.

*Second Disease in Pernicious Anemia. H. Liechti.—p. 172.
Changes in Secretion and in Blood Following Gastric Operations. G. G. Fravi.—p. 174.

Second Disease in Pernicious Anemia.—Liechti maintains that, if a patient with pernicious anemia contracts a second disease, the latter may replace the manifestations of the first. The second disease effects an alteration in the hemopoiesis; it does not, as might be assumed, further develop the megalocytic hyperchromic blood picture. On the contrary, the hemogram has a tendency to assume a hypochromic character with macrocytic or normocytic erythropoiesis. The myelopoiesis, which is usually impaired in pernicious anemia, often shows a considerable increase under the influence of the second disease. If observed early, this alteration in the hemopoiesis may be of great diagnostic significance; not that it indicates the type of disorder, but it does indicate that such a disorder exists, even though its symptomatology is still latent. The author describes case histories to illustrate this. In the first case gastric cancer developed in addition to pernicious anemia. The alteration in the hemopoiesis was observable several months before the gastric symptoms appeared. In the second case pulmonary tuberculosis developed in addition to pernicious anemia. In this case again a hyperchromic hemogram was changed to a hypochromic one. The author concludes from these observations that patients with pernicious anemia are in need of constant supervision of their blood picture not only because of a possible relapse of the pernicious anemia but also because a second, perhaps more malignant, disease may develop and produce alterations in the hemogram. Cases of pernicious anemia which later became complicated by gastric cancer have been reported repeatedly in recent years. The concurrence of these two diseases does not seem to be mere accident. To be sure, in some instances of concurrence the gastric cancer is primary, and anemia with the aspects of the pernicious type develops after the extensive gastric resection.

*Urea in Suppurative Surgical Infections. A. G. Chiariello.—p. 61.
Chemical Changes of Skeletal Muscles from Electrical Trauma. G. Montemartini.—p. 76.

Urea in Surgical Infections.—Chiariello observed the results of local application of urea in the treatment of surgical infections in thirty-one cases. The results were satisfactory. In the first series of experiments he observed the effects of urea in comparison with those of other local treatments (application of olive oil or of a 5 per cent solution of tannic acid or a local aseptic medication) in experimental septic burns. In the second series he compared the evolution of experimental aseptic wounds which were treated by local application of either urea solution or of a local or aseptic medication. The author found that urea has a detergent and deodorant action and that it stimulates regeneration of infected tissues. The results are better in chronic osteomyelitis, suppurated favus of the neck and infiltration of the urinary tract from suppuration than in varicose ulcers of long duration and in some other conditions which are related to factors other than the local ones. The treatment gives satisfactory results when it is administered after performance of the necessary surgical interventions but not otherwise. Urea stimulates autolysis of dead tissues and increases the local defenses of new tissues against the local infection. The action of urea on epithelization is slight. The bactericidal effect of urea is indirect. From the clinical and experimental results the author concludes that urea is of value in the treatment of surgical infections.

60: 25-48 (Jan. 8) 1939

*Mester's Test for Diagnosis of Rheumatic Diseases. G. Braghin.—p. 27.

Mester's Test for Rheumatic Diseases.—Braghin performed Mester's salicylic acid test on a group of 135 persons either normal or suffering from rheumatic or nonrheumatic diseases. The test was carried out by the original technic, which is as follows: Blood is withdrawn from the middle finger of the right hand of fasting patients before and again thirty and sixty minutes after administration of two or three intracutaneous injections of 0.2 cc. each of a sterile 0.1 per cent aqueous solution of salicylic acid, and the number of leukocytes is determined after each withdrawal. The injections are made at the flexor aspect of the right forearm at a distance of about 5 cm. from each other. They are followed by severe pain and burning sensation of short duration and by the formation, at the points of the injections, of wheals which disappear in a few hours. Positive results are shown by transient leukopenia within the first thirty minutes (and in rare cases within the first sixty minutes) after administration of the injections. The diminution of the leukocytes varies from 20 to 50 per cent or more in comparison with figures which existed before administration of the injections. The author reports the results of his observations in tables. The test gave positive results in all forty-five patients (first table) who were suffering from rheumatic diseases which included acute, subacute and chronic rheumatic polyarthritis, rheumatic ankylopoietic spondylarthritis, rheumatic ischalgia, rheumatic fever with cardiac complications and chronic rheumatic iridocyclitis. The number of leukocytes diminished within 30 and 50 per cent but not more than that. The positive results were obtained in forty cases in the blood which was withdrawn thirty minutes after the injection and in five cases in that which was taken sixty minutes after the injection. The test gave negative results in the group of thirty-one patients (second table) who were suffering from nonrheumatic diseases with symptoms similar to those of rheumatic diseases. The group included patients with tuberculosis, syphilis, articular gonococcic infection and gout. The test gave also negative results in a group of fifty-nine persons (third table), including normal persons and patients with other than rheumatic diseases. The author concludes that the test is specific for the diagnosis of rheumatic diseases. The test is a hemoclastic reaction of the type of that described by D'Amato for syphilis rather than an anaphylactic reaction, as the author previously believed.

Riforma Medica, Naples

55: 161-200 (Feb. 4) 1939

Functional Relations Between Spleen and Stomach. L. Gipperich and U. Butturini.—p. 163.
*Chemotherapy in Gonorrhea. M. Muscolino.—p. 170.
Multiple Congenital Malformations of Leg. V. Ferrara.—p. 178.

Sulfanilamide in Gonorrhea.—Muscolino observed 161 patients who had been given sulfanilamide in the treatment of gonorrhea. All but six (girls) were adults. The adults were given the sulfanilamide in daily doses of from 2 to 3 Gm. in cycles of five consecutive days each with intervals of rest for four days, during which time no other drug was administered, until two cycles had been reached and in rare cases four cycles. The six girls, who had vulvovaginitis, were given daily doses of 1 Gm. for four consecutive days followed by intervals of rest of four days, without any other drugs, up to two and rarely three cycles. Local antiseptic lavages of a weak (1:10,000) permanganate solution were administered daily all during the treatment. The latter failed to control the vulvovaginitis in young girls and was soon discontinued in

three adults because of the intolerance of the patients. The treatment controlled gonorrhea in 113 of 152 adults. The symptoms are abated early in the course of the treatment; the secretion is diminished and soon disappears. As observed microscopically, gonococci completely disappear from the secretion. The drug gives the best results in chronic and subacute gonorrhea and their various complications and better results in men than in women. The satisfactory results are permanent. The author observed the behavior of the crasis of the blood and the spermatogenesis during and after administration of sulfanilamide, in the mentioned doses. It had a slightly harmful but transient effect on the crasis of the blood of fifty patients with acute gonorrhea. It did not interfere with spermatogenesis in five normal men or in five cases of acute gonorrhea. Muscolino therefore concludes that sulfanilamide is valuable in the treatment of gonorrhea and that in the mentioned doses it is both efficient and harmless.

Treatment of Benign Uterine Hemorrhages.—Penkert discusses the nature of menstrual hemorrhages and their irregularities in women beyond the age of 40 years. Then he gives his attention to the symptoms of abolished function, pointing out that they are most severe after roentgen castration and other forms of irradiation and that they are much less severe and less frequent, or even entirely absent, after removal of the diseased uterus with preservation of the ovaries. Even though the vaginal total extirpation of the uterus, without the ovaries, is not the ideal treatment of metropathias, as regards the absence of the symptoms of abolished function, as regards the rapidity of recovery and as regards the capacity to work again, it is by far superior to the roentgen castration; the same can be said about the abdominal total removal of the uterus without the adnexa in the presence of large myomas. After stressing the contraindications to the ray treatment of myomas, the author says that every benign uterine hemorrhage requires an exact diagnosis and then there arises the question, What is the best treatment for this patient? Roentgenologic treatment involves on the whole less risk and less responsibility than does an operation. Nevetheless, although the author was one of the first who introduced and advocated the roentgen treatment of myomas and metropathias, many years of observations and some disappointments have brought him to the point at which he resorts to this treatment only with reservations and in specially selected cases. He has come to the conclusion that, in spite of the great dangers that are involved in an operation, surgery is nevertheless the most prompt and best method.

Postpartum Intra-Uterine Interventions. — Geppert demonstrates that the prognosis of postpartum intra-uterine interventions that are carried out in modern clinics can be regarded as favorable as regards morbidity as well as mortality, provided of course the management of the delivery has been under clinical supervision from the beginning. The results obtained with postpartum intra-uterine interventions in the clinic are superior to those obtained in home practice, because the aseptic conditions and the presence of trained persons makes an intervention possible, before great loss of blood has taken place. To be sure, it is generally difficult to foresee disturbances of the period of the after-birth. It is known that they may appear *without* recognizable cause. For this reason a number of parturient women must undergo intra-uterine interventions in the home and thereby are exposed to greater hazards. However, the author thinks that women who in earlier deliveries experienced difficulties during the period of after-birth and those who have had abortions or curettages may expect difficulties in the delivery of the placenta in subsequent confinements and it has to be decided whether for these cases delivery in the clinic might perhaps be advisable.

Acute Venereal Lymphogranuloma.—Reimers reports forty-five cases of acute venereal lymphogranuloma treated at the surgical clinic of the Military Medical School in Canton, China. In smears made from human lymph nodes and infected brain of white mice stained by the Giemsa method, the author found both intracellular and extracellular "granulocorpuscular" elements. However, the author is uncertain as to the practical clinical value of this observation in early diagnosis. In his experience the intracerebral implants of lymph node material or of pus in white mice permits an earlier diagnosis than the Frey antigen, even though it requires not less than eight days. The identity of climatic bubo and of venereal lymphogranuloma was established by the crossed reaction of the European antigen and an antigen prepared by the author. The microscopic examination of the tissues, especially in mixed infections, is as valuable in diagnosis as the Frey reaction. For therapeutic purposes the author divided his cases into the following stages: (1) the stage of abscess formation, (2) the stage of inguinal lymph node enlargement, (3) the stage of iliac lymph node enlargement, (4) the fistulous stage and (5) the residual ulceration. He advocates conservative treatment for the acute stage. For the second and fourth stages he suggests radical removal of the involved glands, while involved iliac lymph nodes are to be operated on only in exceptional cases. On the basis of his observations in several of the cases, syphilis likewise is a factor in the formation of genito-anorectal elephantiasis (esthiomene). The author stresses the point that application of the Frey antigen tests in the differential diagnosis of all chronic inflammatory diseases of the large and small intestine should be of value, because the differentiation of venereal lymphogranuloma from other chronic inflammatory diseases on a clinical basis alone is not possible.

Thyrotoxicosis.—Troell operated in 1,842 cases of thyrotoxicosis during the period from 1930 to 1937. His operative mortality, which up to 1924 amounted to 9.6 per cent, fell considerably after the introduction of compound solution of iodine in 1925. This mortality in 354 surgical cases between January 1925 and October 1930 was 3.3 per cent, while the mortality from that period up to 1937 in 579 surgical cases amounted to 2.6 per cent. In the begining only patients with diffuse exophthalmic goiter were placed on preoperative treatment with compound solution of iodine. Later this treatment was extended to highly toxic cases of nodular goiter. In the cases of nodular goiter of mild toxicity the author used both before and after operation a preparation called "kinifos." This is a preparation consisting of quinine, sodium bromide, sodium phosphate and calcium lactate. The reason for withholding compound solution of iodine from patients with toxic nodular goiter was partly the fear of inducing an iodine thyrotoxicosis and partly the clinical and histologic differences between the two types of the disease. However, the difficulties attending a sharp differentiation of the two types, as well as a careful analysis of individual cases, compelled the author to give up the dualistic concept of thyrotoxicosis and assume instead that the differences in the clinical

picture of the two are rather to be explained by the age and constitution of the patient. The demonstration by Okkels of a hypertrophy of the Golgi apparatus characteristically present in all cases of thyrotoxicosis lends considerable support to the theory of nosologic identity of the two clinical pictures. The average duration of preoperative treatment with compound solution of iodine amounted to ten days. Debilitated patients were given, besides the solution, insulin, blood transfusions and intravenous dextrose. On the completion of the operation the patient was given 1,000 cc. of 5 per cent dextrose solution subcutaneously and the same amount by rectum, the latter with addition of 1.25 cc. of tincture of opium and 2 cc. of compound solution of iodine. Very sick patients and those with a severe postoperative reaction were given twice the amount, with the addition of 5 cc. of the compound solution of iodine in the intravenous dextrose infusion.

*Significance of Histamine and of Its Action as Cause of Late Death After Burns. E. Bernhard-Kreis.—p. 756.

Relation of Insular Apparatus of Pancreas to Gonads.—Hoffmann states that clinical and experimental observations indicate that relations exist between the islands of Langerhans and the ovaries or testes. The glycosurias of pregnancy indicate interrelations between the insular apparatus of the pancreas and the ovaries. She reviews the relations of pancreatic disturbances to the genital functions in women and men, pointing out that diabetes may produce amenorrhea and atrophy of the ovaries and of the uterus. Moreover, diabetic women are frequently sterile. Diabetes in men is frequently accompanied by impotence; in fact, impotence often exists before the diabetes has been recognized. Atrophy of the testes and azoospermia result in some diabetic men. The author further reviews the literature on the pathologic-anatomic changes in the gonads of animals in which diabetes was artificially produced and in the insular apparatus of castrated animals. Since the reports about the effects of castration on the insular apparatus were contradictory, she made morphologic studies on male mice. Mature male mice were castrated and, after various lengths of time, the pancreases of these animals were compared with those of normal animals. Summarizing her observations, the author says that relations exist between the gonads and the insular apparatus of the pancreas because castration is followed by a considerable increase in the incretory tissue. The counting and measuring of the islands indicated that this increase of incretory tissue is the result of an enlargement of existing islands. A relative increase, by reduction of the excretory tissue, could be excluded on the basis of the counting and measuring of the islands. Compared to normal values, the increase in insular tissue amounts to approximately 80 per cent. Enlargement of the islands is accomplished by transformation of excretory tissue into insular tissue. From the fact that castration causes an enlargement of the islands it may be concluded that the gonads exert an inhibiting effect on the insular apparatus but that the pancreas, on the other hand, stimulates the gonads. Whether this mutual modification is direct or whether other organs, such as the hypophysis, intervene is a problem that remains to be solved.

Histamine and Late Deaths After Burns.—According to Bernhard-Kreis, the problem of the ultimate cause of death from burns, particularly of late death, has not been solved. Continuing earlier animal experiments on connections between the mechanism of anaphylactic shock and that of damage by heat, he found that, as regards the changes in the organs, former observations were corroborated. He observed that by the repeated injection of extracts from organs that have been damaged by heat it is possible to produce changes which greatly resemble those which are produced by heat directly. Thus it can be concluded that there are no corroborating factors for direct connections between burns and anaphylaxis. The animals uniformly exhibit the signs of a steadily progressing cachexia no matter whether they have been treated with organic macerations that contained protein or with decoctions and roasting extracts that were free from protein but contained peptones and albumoses. The resulting organic changes are predominantly of the parenchymatous degenerative type; however, a comparison with those resulting from poisoning with pure solutions of histamine reveals that they cannot be ascribed to the fact that histamine acts in the extracts. In the organ extracts, particularly those from the skin and the musculature, the biologic methods of assay did not reveal the presence of histamine except in two unusual cases. This applies to the cold macerations of unchanged native organs as well as to the decoctions and roasting products. The action of these extracts and the action of the comparative processes in the living (scalding) is thus ascribed to roasting products and to peptones and albumoses. Action of histamine or of similarly acting substances (H-substances) must still be rejected.

The Use of Human Fat in Surgery.—Kartavova calls attention to the fact that fat may act as a source of water in patients with disturbed water balance in addition to constituting the principal source of reserve energy of the organism. Utilization of fat for parenteral administration to patients unable to take nourishment by mouth has been attempted from time to time without definite results. The author reports her experiences with parenteral administration of human fat in fifty cases. The method of preparation is as follows: Fat obtained in the course of an operation is washed several times with cold water, cut up into small pieces and placed in an autoclave for from two to two and one-half hours, filtered through four thicknesses of gauze and sterilized by boiling. The resulting substance is a thick, yellow, odorless fluid with neutral reaction. Another source of fat is that taken from cadavers of persons dying suddenly. The average dose injected subcutaneously amounted to 50 cc. As much as 200 cc. could be administered without untoward effects. The injected fat is readily absorbed and produces no ill effects. It is indicated after resection of the stomach, in grave cases of peritonitis with continuous vomiting and in patients exhausted from suppurative disease.

*Diagnosis of Cancer of Pancreas. V. M. Kogan-Yasniy and A. Ya. Altgausen.—p. 611.

Estrogen and Cholesterol in Growth of Neoplasms.—According to Peysakhovich, introduction of large amounts of cholesterol into the organism of an animal with experimental neoplasms (mice and rats) leads to an increase in the average weight and rate of growth of the neoplasm. The mechanism of this effect is bound up with factors having to do with hypercholesterolemia. He believes that lowering of the function of the reticulo-endothelial system, as a result of its partial blockade with cholesterol, is an important factor. Hyperestrogenization in mice and rats leads to a marked increase in the tendency to growth and the weight of all transplanted tumors. Structural

alterations in sex glands, resulting from long continued injections of large doses of endocrine preparations, bring about partial castration, thus creating conditions favoring activation of the growth of neoplastic new formations. Partial castration, in addition, causes a general alteration in the entire system of glands of internal secretion. The author did not observe a synergistic effect when the two substances cholesterol and estrogen were injected simultaneously. The two substances resemble each other in their ability to stimulate the growth of experimental neoplasms.

Cancer of the Pancreas.—Kogan-Yasniy and Altgausen emphasize the difficulty of diagnosis of cancer of the pancreas and its differential diagnosis from cancer of the liver, the biliary tracts and the duodenum and particularly from cancer of the papilla of Vater. The difficulty is due to the fact that the conditions mentioned present a number of similar symptoms, the principal of which is obstructive jaundice. Bergmann's statement that carcinoma of the papilla of Vater and of the duodenum can be diagnosed roentgenologically with considerable accuracy was not confirmed by their clinical experience. The authors emphasize that the determining factor in the differential diagnosis between cancer of the pancreas and cancer of the papilla of Vater is to be found in the functional disturbances of the pancreas. Glycosuria, which results from the invasion of the insular apparatus, is present in a considerable portion of the cases of pancreatic cancer. These cases are likewise characterized by rapid emaciation resulting from diminution of oxidizing processes and from inadequate assimilation of nourishment. Microscopic examination of feces reveals the absence or diminution of pancreatic ferments by the presence of neutral fat and undigested muscle fibers. In view of the fact that trypsin converts the amino acids leucine and tyrosine into indole, the quantitative determination of indican can serve as an accurate index of the excretory function of the pancreas. The authors cite several cases in which the determination of the internal and external pancreatic secretions made it possible to differentiate between carcinoma of the pancreas and that of the papilla of Vater. Their clinical experience gives support to an old statement of Leube that marked indicanuria speaks against cancer of the head of the pancreas.

Relapsing Gastric Hemorrhages and Their Treatment.—Hesser says that acute gastric hemorrhage still presents many unsolved problems. During recent years it has attracted interest, principally owing to a certain new attitude in the matter of treatment. Surgeons have urged that operations should be performed in many of these cases during the acute stage, to prevent threatened death from loss of blood. Nevertheless, in medical circles conservative therapy is still recommended, especially since Holmgren and Meulengracht claimed that the prognosis had been materially improved by the abandonment of starvation diet and by giving food in a liquid or semisolid form in sufficient quantities from the beginning of the treatment for gastric ulcers. In view of the fact that bleeding gastric ulcers are a common complaint, the question of treatment is of great practical importance. In this paper the author gives his attention chiefly to the relapsing gastric hemorrhages, which, judging from his own experience, constitute a substantial proportion of the large group of acute gastric hemorrhages. Analyzing a material of 406 patients with gastric hemorrhages, he says that in 284 one hemorrhage occurred and that in 122 two or more hemorrhages occurred; that is, relapses occurred in about 30 per cent of the cases. Among the relapsing cases one relapse is most usual (57 per cent) but two or more relapses are by no means unusual (up to twenty-two relapses in one case). The age of predilection for relapses is on the whole the same as for hemorrhages in general; that is, the frequency predominates in the ages between 30 and 60 years. In the matter of distribution by sex the same rule applies to relapses as to primary hemorrhages, namely that they are much more frequent in men than in women (more than twice as frequent). Regarding the anatomic situation of the ulcer, the author says that duodenal ulcers predominate considerably over ventricular ulcers (twice as frequent). Discussing the prognosis, he says that he observed four deaths in 122 cases of relapsing hemorrhage. The four patients who died were a man aged 84, a woman aged 79, a man aged 64 and a woman aged 41, which shows that, as in the case of primary hemorrhages, the more advanced ages seem most threatened. The author's material included thirty cases in which gastric operations were performed (gastro-enterostomy, and Billroth I and Billroth II) and gastric hemorrhages recurred once or more often. From this it appears that ventricular operations are by no means effective prophylactic measures against hemorrhages.

Essential Thrombopenia (Morbus Maculosus Werlhofii).—Heinild says that essential thrombopenia (idiopathic purpura with thrombocytopenia or hemorrhagic purpura) is a disease of unknown origin characterized by spontaneous hemorrhage of the skin and mucous membranes. Hematologic examination shows a great decrease in the number of blood platelets, absence or retardation of retraction of the clot, prolongation of the bleeding time and a decrease in the capillary resistance. The disease may have an acute or a chronic course. On the basis of the present status of knowledge on thrombopenic conditions, four groups can be differentiated: (1) essential thrombopenia, (2) symptomatic thrombopenia, (3) hyperergic thrombopenia and (4) hypersplenic thrombopenia. After giving the characteristics of these four groups the author reports and analyzes six cases of his own observation. He shows that the first case must be designated as a symptomatic thrombopenia of unknown origin. In this case the course of the disease was malignant, affecting chiefly the bone marrow and, as found at necropsy, toxic changes developed in the lymph glands. Cases 2, 3, 4 and 5 present aspects which closely correspond to the definition of chronic essential thrombopenia. Case 6 is of interest because it is one of those transitional cases which should be placed between the real forms of purpura without decrease in platelets (idiopathic purpura) and essential thrombopenia. The author thinks that the observations of several other investigators and his own investigations justify the theory that deficiency of the capillaries is constantly present and is of fundamental importance in this disease because its degree of severity coincides with the clinical manifestations. But of course it must be remembered that the constantly present symptom thrombopenia is of equal importance. It is of special interest that essential thrombopenia frequently appears at the time of the climacteric, that at this time of life a tendency to purpura has previously been proved experimentally, and that the so-called medicamental allergic thrombopenia seems to have a predilection to appear at this period. Hence it is natural to suppose that disturbances in the endocrine balance also predispose to the development of so-called essential thrombopenia. In this publication it has been proved that the thrombopenic condition is not due to the cessation of the production of estrogen as such. Nor are endocrine variations the only predisposing causes, for the disease often appears in early childhood. This is a warning against the expectation of good results from the conventional treatment of thrombopenic conditions. It is evident that while symptomatic thrombopenia is frequently caused by fundamental disturbances in the hemopoietic system and hence beforehand renders any therapy unavailing, allergic thrombopenia on the other hand has a tendency to spontaneous recovery. The good effect of the splenectomy is indisputable and it seems due more to the improved function of the capillaries than to any increase in the number of platelets. There is no doubt that splenectomy would produce a good result in cases 2, 3, 4 and 5. The present examination, however, does show that conservative treatment, when consistently effected, may cause a considerable improvement in the function of the capillaries. It will be a problem for the future to elucidate the origin of essential thrombopenia.

ANGINA PECTORIS AND CARDIAC INFARCTION FROM TRAUMA OR UNUSUAL EFFORT

WITH A CONSIDERATION OF CERTAIN MEDICOLEGAL ASPECTS

ERNST P. BOAS, M.D.

NEW YORK

Can a nonpenetrating injury to the chest or severe bodily effort directly provoke cardiac infarction or lead to changes in the heart that give rise to the syndrome of angina pectoris? This question, arising so frequently in connection with claims under workmen's compensation acts, has not yet been satisfactorily answered. The preponderant opinion at present seems to be that trauma and effort so rarely precede the onset of coronary thrombosis that their association is just coincidental. This thesis has been particularly elaborated by Master and his associates.[1] They have analyzed the events attending 530 attacks of coronary thrombosis. They find that 22 per cent of attacks occur when the patient is at rest, 20 per cent while he is asleep, 18 per cent while he is walking, 14 per cent during mild activity and 5 per cent during moderate activity. They point out that since half of the day of normal persons is spent in mild or moderate activity, one might well expect that half of all attacks of coronary thrombosis would occur during this period. The fact that 36.9 per cent of attacks occurred during such mild activity therefore is interpreted as a mere temporal, not a causal, association. Only 2 per cent of the attacks followed unusual exertion, and 5 per cent followed excitement. On the basis of this low incidence of coronary thrombosis following unusual stress the authors conclude that in such cases the association of the stress and the vascular occlusion is only accidental. Coronary thrombosis following operation was encountered in 4 per cent of their series. In this instance, however, the authors do not apply the criteria of probability employed in their discussion of the effect of exertion on coronary thrombosis but on general grounds conclude that operation is a factor that may initiate coronary thrombosis.[2]

These deductions are inconsistent. I fully agree with Master that coronary thrombosis very often occurs while the individual is at rest or asleep and that in many cases no antecedent injury or effort has taken place. But to argue from this that such accidents are not competent causes of coronary thrombosis appears incorrect. The fact that pneumothorax is due usually to pulmonary tuberculosis or to the rupture of an emphysematous bleb does not negate the fact that it may follow trauma to the chest; or that cerebral hemorrhage is caused usually by disease of the cerebral arteries that it may not be due to trauma to the head.

In my experience trauma or bodily effort may directly induce closure of a coronary artery with cardiac infarction or may initiate the syndrome of angina pectoris. This occurs with sufficient frequency to be of practical clinical importance as well as of medicolegal significance. I propose in this paper to present evidence from the literature as well as from my personal experience that injuries to the chest or severe effort may produce signs and symptoms of injury or impairment of the coronary arterial circulation.

TRAUMATIC NONPENETRATING INJURIES OF THE HEART

Many cases of injury to the myocardium following nonpenetrating injuries to the chest have been observed at necropsy and reported in the literature. In Warburg's[3] recent monograph 174 instances of myocardial lesions due to nonpenetrating traumatic injuries to the chest are abstracted from the literature. To these he adds thirteen new cases of his own. Many types of myocardial injury are described, ranging from rupture of one of the cardiac chambers to scattered small myocardial hemorrhages. In a number of the cases in his series, as well as in others not included in his book, damage to the coronary arteries or the anginal syndrome has been observed after this type of injury. A few such cases will be briefly cited.

A man aged 45, struck in the precordium by a wagon shaft, was unconscious for several minutes and when consciousness returned complained of severe pain in the chest, back, left shoulder and left arm.[4] Physical examination revealed no cardiac abnormalities. The patient continued to suffer from cardiac pain, which came particularly when he was active and which prevented him from climbing stairs. He died suddenly six months after the accident. At necropsy organized thrombi were found in the anterior descending branch of the left and in the circumflex branch of the right coronary artery. The myocardium was scarred and there was an aneurysm of the left ventricle at the apex. There was advanced arteriosclerosis of the descending aorta between the aortic isthmus and the diaphragm.

A boy aged 12 years was run over by a wagon and six ribs of the left side of the chest were fractured.[5] After recovery from the accident the boy was apparently well for twelve years, except

for occasional attacks of palpitation and vomiting. At the age of 24 he began having attacks of paroxysmal auricular flutter, some of which lasted as long as a week. Heart failure developed in some of the attacks. He died suddenly at the age of 25. Necropsy revealed an aneurysm of the anterior aspect of the left ventricle. The anterior descending branch of the left coronary artery stopped abruptly at the upper edge of the aneurysm. The authors concluded that it had been destroyed by the trauma thirteen years previously.

A man aged 40 who had been perfectly well fell on his back while skiing.[6] When he arose he felt nauseated, but he kept on. A quarter of an hour later he collapsed, vomited and complained of severe precordial pressure and angor animi. The pulse was irregular, the heart sounds faint and the blood pressure 95 systolic, 55 diastolic. In a short time the liver became enlarged. Fever and leukocytosis followed. An electrocardiogram taken twenty-four hours after the fall showed a high take-off of the T waves in leads 2 and 3. A subsequent electrocardiogram showed a typical Q_3-T_3 pattern.

A man aged 57, who was accidentally struck over the precordium by a golf ball, was in a state of shock for fifteen minutes but gradually recovered, so that he was able to attend to his business the following two days.[7] On the night of the third day there was an attack of angina pectoris, with electrocardiographic evidence of cardiac infarction. Prior to the injury there had been no symptoms of coronary disease.

Bean[8] described three cases of coronary thrombosis following trauma. Beck[9] as well as Munck[10] has described contusions of the heart with hemorrhage into the myocardium, verified at necropsy.

Experimental studies have confirmed these clinical observations. Kissane, Fidler and Koons[11] struck blows on the chests of anesthetized dogs. Electrocardiographic abnormalities, especially changes in the RT segments, were observed. Pathologic studies revealed subendocardial and subpericardial hemorrhages. In three cases in which the electrocardiograms were abnormal, no lesions were discovered. The most complete studies are those of Schlomka.[12] Most of the experiments were carried out on rabbits and cats; in two cases dogs were used. The precordium was struck with blows of moderate intensity. Rarely was the blow sufficiently strong to cause rupture of the heart or death. Frequent electrocardiograms were taken. Characteristic and common observations were sinus bradycardia (even when the vagus had previously been cut), extrasystoles, ventricular tachycardia, ventricular fibrillation, auricular fibrillation and partial and complete heart block. In many instances typical "coronary" T waves, with high take-offs, were encountered. X-ray studies usually revealed cardiac dilatation. In many cases the electrocardiographic changes rapidly returned to normal; in not a few there was permanent cardiac damage, manifested by persistent electrocardiographic changes and cardiac enlargement. Cardiac abnormalities occurred particularly when the precordium itself was struck; injuries to other parts of the chest rarely produced cardiac damage. T wave changes occurred with particular frequency from a quick sharp blow with a small object concentrated in a small area, particularly directly over the sternum or the apex. Pathologic changes were chiefly focal myocardial hemorrhages. In some animals who succumbed to the trauma no anatomic lesions were discovered. Some of the rabbits used had previously been sensitized to horse serum. In these, anemic infarcts of the myocardium were very common. From his own studies and from a review of the clinical, physiologic and pathologic literature Schlomka concluded that blows sharply localized to the precordial area produce a spasm of the coronary arteries and that, depending on the duration of the ischemia, the changes in the myocardium may be reversible or irreversible. The coronary arteries themselves may be injured by the ischemia so that permanent damage to these vessels may ensue. He drew a parallel between such coronary spasms and the segmental arterial spasm observed in the case of gunshot wounds that penetrate the tissues near arteries of the extremities. Arterial spasm following arterial embolism may offer an analogous phenomenon.

Kohn[13] was the first to describe the syndrome of traumatic angina pectoris. Careful students of the subject such as Warburg,[3] Schlomka,[12] Beck[9] and Barber[14] all agree that symptoms of angina pectoris may be initiated by traumatic nonpenetrating injuries to the chest in the precordial region. I entertain the same conviction. The following case, which I observed, offers convincing evidence of the validity of this conclusion:

CASE 1.—A man aged 62, who had worked for seventeen years as a plumber, doing heavy work, carrying bathtubs into buildings and the like, without any symptoms whatever, was cleaning a sewer pipe, Nov. 7, 1935, which had become blocked. For this work a heavy cable was fed into the sewer by one man and extracted on the other side by the patient. The cable was new and had considerable spring. The patient was winding the cable into a coil on the receiving end when it suddenly sprang and struck him with considerable force in the left lower part of the chest. He was stunned. Things became dark before his eyes and he had to remain leaning against the wall for half an hour. Then with some effort he finished the job but went to the feeding end of the cable, where the work is lighter. He managed to work slowly and intermittently for the rest of the day. In the afternoon local pain and swelling appeared on his chest where he was struck, and when he returned home his wife remarked that his face looked pale and drawn. The next morning he returned to work, but slight effort, such as using a wrench, provoked pain in the precordium, compelling him to rest every half hour or so. On this day and on the following days he noted increasing difficulty in walking, so that by the fourth day he was compelled to stop, after walking five blocks, by a sense of choking in the left side of the chest, which radiated to the left side of the neck. He continued to work with difficulty for ten days. November 25 he experienced precordial pain which become progressively more severe, which lasted all night and for which he was given a hypodermic injection of morphine. He remained in bed eight weeks after this attack. Ever since he has had angina pectoris on effort. Fluoroscopic examination June 24, 1938, revealed much enlargement of the left ventricle. The first heart sound was of good quality. There was a systolic murmur at the apex. The blood pressure was 110 systolic, 80 diastolic. The electrocardiogram showed low voltage and slurring of the QRS complex in all leads, a Q wave and a flat T wave in lead 1, and a large Q wave and negative T wave in lead 4.

CORONARY OCCLUSION OR ANGINA PECTORIS INDUCED BY SEVERE OR UNUSUAL BODILY EFFORT

Ever since Kohn in 1929 set up the syndrome of angina pectoris traumatica there have been repeated references in the literature to coronary artery occlusion following severe bodily effort. Fitzhugh and Hamilton[15] described many cases of coronary thrombosis following unusual or violent physical exertion and concluded that the effort induced the arterial occlusion. In their experience "more often than not fatal anginas or coronary occlusions were immediately preceded by unusual departures from ordinary habits of living."

Kampmann[16] described the case of a man aged 43 who was pulled to the ground violently when the crank handle of a bus that he was cranking kicked back. Immediately he felt sharp precordial pain and became dizzy. He was able to drive a little farther but half an hour after the accident vomited and experienced severe precordial pain, broke out in a cold sweat and became pulseless and cyanotic. He slowly improved. The following day his heart rate was 32. In the subsequent eight days it rose slowly to 60, but he had a number of attacks of Stokes-Adams syncope. Two years later he still had precordial pain on exertion. The heart sounds were faint; the electrocardiogram showed a Q_3-T_3 pattern and a PR interval of 0.21 second. This man experienced an infarction of the posterior aspect of his left ventricle after the accident and with this a complete heart block. The author referred to other reported cases of traumatic heart block.

Phipps,[17] without giving detailed clinical histories that make possible a critical evaluation of his data, reported that in 40 per cent of cases coronary thrombosis occurred under conditions of physical stress and that in 13 per cent it occurred during exercise. Luten[18] found effort rarely associated with coronary thrombosis, but it is chiefly Master who denies that effort is a competent producing cause of coronary thrombosis.

Bean and Mills[19] in a recent study of 1,640 attacks of coronary occlusion found that in northern cities these attacks occur with much greater frequency in winter than in summer. There were twice as many attacks in January as in August. They conclude that the greater frequency of infections and the heightened metabolism in cold weather increase the work of the heart and so add to the hazards to which these patients are exposed.

I have examined and studied twenty-five patients in whom coronary occlusion appears to have been directly induced by severe or unusual exertion. The following cases illustrate this sequence:

CASE 2.—I. R., a man aged 47, seen July 27, 1937, had known for about a year that his blood pressure ranged between 150 and 160. He had, however, felt quite well except for headaches and had worked hard as a painter without symptoms. July 6, while lifting an 85 pound can of paint, he experienced sudden pain in the left arm and in both jaws. He dropped the can and in a few moments felt well. Five hours later, while he was rolling a barrel up an incline, he experienced some pain in the left arm and jaw, as well as in the midchest. The pain became very severe, lasted eight hours and was associated with a sense of choking. He remained in bed for three weeks, until the time of his examination. He was a well built man. Fluoroscopic examination revealed slight enlargement of the left ventricle. The heart sounds were of good quality. There were no murmurs. The blood pressure was 130 systolic, 80 diastolic. The electrocardiogram showed Q waves and sharply negative T waves in leads 2 and 3. He was again seen two months later. He had no symptoms, but the blood pressure had risen to 160 systolic and 100 diastolic. He was awarded compensation under the workmen's compensation law of New York State.

CASE 3.—M. S., a man aged 53, who had always been perfectly well and strong and had no knowledge of previous heart disease or high blood pressure, at about 9:30 a. m. May 22, 1937, lifted a roll of pattern paper, weighing 180 pounds, in order to place it on a table. He experienced sudden sharp and pressing pain in the left lower part of the chest, which radiated to the back of the left side of the chest. For a few minutes he was unable to catch his breath and unable to straighten up. Then he coughed up a small amount of blood with some relief. He immediately stopped work and was driven home by a friend. Severe pain continued throughout the day, in spite of the fact that he received a number of hypodermic injections. An electrocardiogram taken May 24 showed an elevation of the RT segment in leads 1 and 2, a marked depression of the RT segment, a negative T wave and a deep Q wave in lead 4. May 27 he was taken to the Manhattan General Hospital, where he stayed until July 12. Here a diagnosis of coronary thrombosis was made. An electrocardiogram taken July 12 showed negative cove plane T waves in leads 1 and 2, very low voltage in all leads, Q waves in leads 2 and 3 and a negative T wave and a Q wave in lead 4. August 22 he was admitted to the Israel-Zion Hospital, complaining of shortness of breath and precordial pain, and remained in this hospital until October 14. Here a diagnosis of left ventricular insufficiency was made in addition to that of coronary thrombosis. He has been in bed most of the time since then. When he attempts to walk he experiences precordial pain and pain in the back which compel him to rest. Bending too provokes such pain. Sept. 20, 1938, fluoroscopic and x-ray examination revealed marked generalized dilatation of the aorta and a great enlargement of the heart, involving chiefly the left ventricle and auricle. Along the lower half of the left border of the heart there was a marked bulge, which on fluoroscopic examination showed practically no pulsation. On the x-ray film one saw marking the edge of this bulge a crescentic shadow, which apparently represented calcification. The heart sounds were feeble. There were no murmurs. The blood pressure was 130 systolic, 90 diastolic. The electrocardiogram showed low voltage in all leads, Q waves in leads 1, 2 and 4, an elevated RT segment, a negative T wave in leads 1 and 4 and a W shaped QRS complex in leads 2 and 3.

CASE 4.—S. N., a man aged 44, first observed April 2, 1937, had had occasional attacks of midabdominal cramps three years previously unrelated to meals. At that time he was unable to walk or climb stairs as readily as formerly, because he became tired and slightly dyspneic. After a few months these symptoms disappeared, but they recurred in January 1937. A gastrointestinal x-ray series suggested the presence of a peptic ulcer. In March he noted a heaviness in his chest, which was persistent but was not intensified by excitement. March 29, while lifting a 50 pound package, he experienced severe substernal pain, was unable to catch his breath and collapsed. The pain lasted about fifteen minues. He went home by subway, stayed in bed for one day and had no further pain. He was seen four days after the accident. Fluoroscopic examination revealed a heart of normal size and configuration. The heart sounds were dull. There were no murmurs. The blood pressure was 190 systolic, 60 diastolic. The electrocardiogram showed elevation of the RT segment in leads 1, 2 and 4. An electrocardiogram taken April 16 showed a diphasic T wave in lead 1, a depressed RT segment in leads 2 and 3 and an elevated RT segment in lead 4. He was seen at intervals during the following one and a half years, and during this time no additional symptoms developed. He applied for compensation under the workmen's compensation act of New York state but his claim was disallowed.

19. Bean, W. B., and Mills, C. A.: Coronary Occlusion, Heart Failure and Environmental Temperatures, Am. Heart J. **16**: 701 (Dec.) 1938.

CASE 5.—S. S., a man aged 49, first observed Nov. 18, 1935, had been perfectly well until three weeks previously, when, while carrying a 60 pound package up one flight from the cellar, he experienced substernal pressure, which lasted about five minutes. This was unassociated with sweating. He continued work but from that time on noted that on working too hard or on walking three blocks he would experience substernal pressure and pain, which would compel him to stop his activities. He was well built. Fluoroscopic examination revealed a heart of normal size and configuration. The first heart sound was split. There were no murmurs. The blood pressure was 130 systolic, 90 diastolic. The electrocardiogram was normal except for a very low T wave in lead 4. He was seen again in February 1936; the symptoms were unchanged. The T wave in lead 4 was now of normal size. He was last seen Nov. 20, 1936. His anginal symptoms persisted.

CASE 6.—H. T. in 1926, when he was 35 years old, was driving a new truck and the motor stalled. He had to crank the engine. This took some time and effort because the motor was new. When he got back into his seat and began to drive away, he experienced pain in the region of the left elbow and some distress in the left side of the chest and had difficulty in catching his breath. He was compelled to stop the truck and get out and walk to the nearest subway station. The original elbow pain stopped after about two minutes but recurred as he walked and compelled him to make his way slowly. He then rested for five weeks and felt quite well until 1936. He had changed to a lighter occupation. In 1936 he began to experience substernal pressure and difficulty in breathing on walking a few blocks, compelling him to rest. These symptoms have continued. I examined him in May 1938. Fluoroscopic examination revealed a transverse heart of normal size. The first heart sound was a bit dull. There were no murmurs. The blood pressure was 140 systolic, 90 diastolic. The electrocardiogram was normal. He was seen again in October 1938. The symptoms of angina pectoris had persisted, but there had been no prolonged attacks of pain. Physical examination disclosed no new developments, but the electrocardiogram now showed a depressed RT segment in lead 1 and a sharply negative T wave in lead 4.

CASE 7.—P. L., a man aged 43, who had worked at his occupation as a painter without any symptoms whatever until July 12, 1937, on this day started work an hour late and rushed to catch up. He was sizing some partitions with a sponge and working very fast. After forty-five minutes he began to sweat and became dizzy. He then experienced a tearing pain to the left of the sternum, which was followed by a constricting sensation, and broke out into a cold sweat. Hypodermic medication was given and he was taken to a hospital, where he stayed for four weeks and where an electrocardiogram showing infarction of the left ventricle was obtained. After discharge from the hospital he still had frequent precordial pain, unrelated to exertion, although greater exertion caused some difficulty in breathing. He was, however, able to resume his work. Fluoroscopic examination September 28 revealed slight enlargement of the left ventricle and some dilatation and elongation of the aorta. The heart sounds were of good quality. There were no murmurs. The blood pressure was 120 systolic, 70 diastolic. The electrocardiogram showed a flat T wave in lead 2 and a sharply negative T wave in lead 3. He applied for compensation under the workmen's compensation laws of New York state, but his claim was disallowed.

CASE 8.—J. B., a man aged 48, first observed Dec. 22, 1936, had had an attack of pressure in the upper part of the abdomen, sweating and collapse five weeks previously, which lasted for ten minutes. He was in bed for ten days and had no recurrence of the pain. He was then well and was working as a hotel keeper. December 20 he had an argument with two drunken men and threw them downstairs and immediately afterward dragged a drunken woman up two flights of stairs. When he reached the top of the stairs he broke out into a cold sweat and was unable to move. He then experienced substernal pain and difficulty in breathing. He was seen two days after this occurrence. He was febrile and appeared ill. There were a few rales at the bases of the lungs. The heart sounds were feeble. The heart rate was rapid. He was seen subsequently on March 25, 1937. Fluoroscopic examination revealed much enlargement of the left ventricle and some enlargement of the left auricle. The first heart sound was faint. The pulmonic second sound was accentuated. There were no murmurs. The blood pressure was 90 systolic, 60 diastolic. The electrocardiogram showed low voltage and slurring of the QRS complex in all leads and Q waves and negative T waves in leads 1 and 4.

CASE 9.—B. S., a man aged 55, first seen in February 1938, was suddenly seized nine years previously, while dancing after a wedding dinner, with substernal pressure which developed into severe pain and was associated with cold sweat. The pain lasted about four hours and was relieved by hypodermic medication. He was in bed for eight weeks. Ever since, walking two blocks would provoke substernal pressure, compelling him to rest. During the three months prior to his present examination, anginal attacks would come on at rest and there had been a number of attacks of paroxysmal dyspnea. Physical examination revealed a few rales at the bases of both lungs. Fluoroscopic examination revealed great enlargement of the left ventricle and of the left auricle. The first heart sound was quite faint and split. The second sound at the apex was reduplicated. There was a systolic murmur at the apex. The blood pressure was 115 systolic, 70 diastolic. The electrocardiogram revealed bundle branch block.

CASE 10.—M. E., a man aged 47, first observed in December 1934, for several years had had some heartburn after eating but was otherwise well. Eleven weeks previously, during intercourse, he experienced pressing pain to the left of the sternum, which radiated down the left arm, and he broke out into a cold sweat. The pain lasted about fifteen minutes and was relieved by a hypodermic injection. He went to work the next day; he again broke out into a cold sweat, feared that another attack was coming on and went to a hospital, where he stayed for four weeks. After discharge from the hospital he noted that walking six blocks or so during cold weather would provoke substernal pressure which compelled him to stop. Fluoroscopic examination revealed some enlargement of the left ventricle. The first heart sound was dull. Both basic second sounds were accentuated. There was a systolic murmur at the aortic area. The blood pressure was 110 systolic, 80 diastolic. The electrocardiogram showed an elevated RT segment with a diphasic T wave and a Q wave in lead 1, a slightly depressed RT segment with a diphasic T wave in lead 3 and a deep Q wave and a negative T wave in lead 4. He was seen again in December 1937, still complaining of angina pectoris on exertion. The electrocardiogram now showed a sharply negative T wave in lead 1, and the T wave in lead 4 had become positive.

CASE 11.—A. N., a man aged 47, who had in July 1930 experienced slight distress in the lower anterior part of the chest while playing ball, would stop when experiencing pain. Oct. 18, 1937, while playing football, he experienced sudden pain in the anterior part of the chest, as though he were in a vice, and broke out into a cold sweat. Severe pain lasted one-half hour and milder pain lasted for two days. The following day his temperature rose to 101 F. He stayed in bed for six days. After this he noted that walking or climbing stairs would provoke substernal pain, compelling him to rest. He was a stockily built man. Fluoroscopic examination October 28 revealed moderate enlargement of the left ventricle and left auricle. The first heart sound was dull. There were no murmurs. The blood pressure was 110 systolic, 70 diastolic. The electrocardiogram showed slurring of the QRS complex and Q waves and sharply negative T waves in leads 2 and 3.

CASE 12.—I. D., a man aged 49, who had been complaining for one and a half years of epigastric burning one or two hours after meals, relieved by sodium bicarbonate or milk, occasionally was awakened at night by this pain. Jan. 18, 1936, while trudging through a heavy snowfall on a very cold day, he began to experience cramplike pain behind the sternum, which radiated to the left upper extremity. He began to sweat. The pain slowly became worse, and he returned home and was given a hypodermic injection a few hours later. Intermittent pain continued for two days and he remained in bed for two weeks. He was seen February 8. He was a stout man of high color. Fluoroscopic examination revealed a heart of normal size and configuration. The heart sounds were of good quality. There were no murmurs. The blood pressure was 135 systolic, 80 diastolic. The

electrocardiogram showed a small Q wave and a low T wave in lead 1 and a deep Q wave and sharply negative T wave in lead 4.

CASE 13.—M. B., a man aged 45, had had a very hard day Sept. 21, 1938, delivering furniture. It was raining heavily and he was wet to the skin. Indeed the weather was so inclement that the driver of the furniture truck telephoned his employer a number of times asking for permission to postpone deliveries to another day, but permission was refused. Toward the end of the day, while the patient was carrying a chifforobe up a second flight of stairs and while he was lifting it high over the banister to make a turn at the landing, he suddenly felt as though something had snapped behind the lower part of the sternum. This was immediately followed by severe pressure across the lower part of the chest, which radiated to the lower pectoral area. He made his way down the stairs, collapsed and was unconscious for four hours. He was taken to a hospital, where he remained for six weeks. After his discharge from the hospital, walking five blocks always provoked sharp parasternal pain on the left, which radiated to the back and which compelled him to rest. Fluoroscopic examination December 30 revealed slight enlargement of both ventricles. The heart sounds were dull. There were no murmurs. The blood pressure was 95 systolic, 70 diastolic. The electrocardiogram had a very low T wave in lead 1 and a Q wave and negative T wave in lead 4.

CASE 14.—S. S., first observed in August 1930, when he was 58, at that time had no symptoms referable to the heart. He had an old tuberculous lesion at both apexes. The left ventricle was slightly enlarged and the aorta a bit dilated and dense. The heart sounds were of good quality. The blood pressure was 160 systolic, 100 diastolic. The electrocardiogram showed only left axis deviation and low voltage. In November 1934 he began to experience substernal pressure and epigastric pain while at work and while walking. The pain would compel him to rest. Feb. 22, 1935, while walking to work during a blizzard, he experienced severe substernal pressure and great weakness. Nevertheless he went to his shop and went to work, and four hours later, while lifting a heavy machine, he became very weak, broke out into a profuse sweat and fainted. Fluoroscopic examination four days later, February 26, revealed that the heart was of the vertical type and not enlarged. The heart sounds were of good quality. There was a systolic murmur at the apex. The blood pressure was 140 systolic, 80 diastolic. The electrocardiogram showed a depressed RT segment, with a diphasic T wave in lead 2 and a Q wave and sharply negative T wave in lead 3. Angina pectoris on slight exertion persisted. He applied for compensation under the workmen's compensation laws of New York State. This case differs from the others in that the symptoms suggesting coronary thrombosis occurred four hours before he went to work and were apparently precipitated by the effort of walking in a snow storm. The final collapse occurred when he overexerted himself four hours after the beginning of the symptoms of coronary thrombosis. In this case the exertion of walking in the snow storm rather than the lifting of a heavy machine must be regarded as the cause of the coronary thrombosis.

These clinical observations, together with those of other authors, warrant the conclusion that the syndrome of coronary occlusion may be induced by a nonpenetrating injury to the chest or by unusual effort and that the same causes may initiate the syndrome of angina pectoris. The reluctance of many clinicians to accept a causal relationship between these phenomena is due in part to the fact that when an injury occurs during work the patient naturally seeks to establish that the work as such was responsible for his disability. He may wittingly or unwittingly construct a logical series of events leading up to his injury. There is a universal tendency among patients to ascribe their illnesses to some concrete indiscretion or accident. Of the fourteen cases that I have presented, only five involved a problem of workmen's compensation. In the others the patient had nothing to gain by ascribing his illness to an unusual effort.

Inability to visualize the mechanism by which lesions of the coronary arteries may be induced by trauma or by bodily effort has further retarded the acceptance of a causal relationship between these events. Recent pathologic studies throw some light on this problem. The manner in which nonpenetrating injuries of the chest can cause myocardial damage has been discussed, and experimental and postmortem evidence has been presented to prove that such traumatic lesions of the heart actually occur.

The way in which unusual bodily effort or strain can induce acute changes in the coronary arteries and in the coronary circulation is suggested by several anatomic studies. Leary [20] states that rupture of an atheromatous cavity of the wall of a coronary artery into the lumen is the standard terminal lesion in older persons dying of coronary thrombosis.

Paterson [21] has studied intimal hemorrhages of the coronary arteries, which are due apparently to rupture of capillaries in the arterial wall. Such intimal hemorrhages are commonly found in recently thrombosed coronary arteries. His studies suggest that capillary rupture and intimal hemorrhage are closely concerned with the formation of most coronary thrombi. Thrombosis in the lumen of a coronary artery may be initiated by diffusion of blood from an intimal hemorrhage into the lumen, by necrosis of the intima or by retrograde capillary thrombosis. Paterson points out that during periods of physical stress a rise in pressure in the capillaries of the intima may occur, causing their rupture. Complete closure of a coronary artery by a thrombus may occur hours or days after the original capillary hemorrhage.

Winternitz [22] has demonstrated the rich capillary network that is found in the arterial wall, particularly in the neighborhood of sclerotic areas, and has shown that hemorrhages into the intima are frequently the precipitating factors in arterial thrombosis.

Wartman [23] has described six cases of complete occlusion of a sclerotic coronary artery by a large hemorrhage into its wall. In one of these cases an intra-arterial thrombus was associated with the intramural hemorrhage. In all cases death was caused by the hemorrhagic arterial occlusion. Winternitz [22] observed similar cases.

These anatomic studies suggest how unusual exertion may bring about coronary artery occlusion. With physical effort there is a sudden alteration of arterial pressure, cardiac action is increased, rupture of one of the capillaries or sinusoids in the arterial wall may occur, or a softened atheromatous plaque may rupture into the arterial lumen. If the hemorrhage is large there may be almost immediate occlusion of a coronary artery; if the hemorrhage is small or slow or if it is followed by a gradually growing mural thrombus the occlusion may develop slowly or remain incomplete. Thus the concept of coronary occlusion and of angina pectoris induced by physical exertion established by

23. Wartman, W. B.: Occlusion of Coronary Arteries by Hemorrhage into Their Walls, Am. Heart. J. **15**: 459 (April) 1938.

discriminating clinical observation finds support and confirmation in dissections of diseased arteries. It follows that when symptoms of coronary artery disease are induced by physical strain, even when the patient has had no preceding symptoms, there have most likely been antecedent anatomic lesions of the coronary arteries. When such symptoms follow nonpenetrating blows to the precordium no such preexisting arterial disease need be predicated.

CRITERIA FOR DIAGNOSIS

These cases often give rise to legal issues, in particular in connection with workmen's compensation acts. The question arises whether the particular injury or effort was a competent producing cause of the symptoms. This can be answered only by a careful evaluation of the succession of events in each individual case, with due recognition of the fact that patients tend to ascribe their illnesses to some unusual experience which actually may have no significance.

When trauma or effort damages the heart, cardiac symptoms, with rare exceptions, develop almost immediately. Precordial pain or breathlessness or both are common and compel the patient to stop whatever he is doing. There may be dizziness, fainting or shock, but these signs may be missing. Complete collapse need not occur and often, after a short rest, the patient is able to carry on for a while or is able to make his own way home. Immediate examination of the heart may not reveal any significant abnormalities. Warburg [3] reported that "fifteen of the fifty-one indubitable cases that were examined post mortem did not immediately after the trauma present such symptoms that there was reason to presume that the heart had been injured."

There is considerable variation in the time that elapses before the full symptoms and incapacity develop. In many instances extensive cardiac damage occurs immediately after the accident or follows within a few hours. In others there is a free interval of many hours or even of several days between the accident and the development of major cardiac damage, and during this interim the patient may complain of little beyond weakness and some uneasiness in the chest. In still other cases there are continuous symptoms of minor cardiac embarrassment after the accident, but these may not be severe enough to incapacitate the patient. Finally after days or even weeks a complete coronary occlusion occurs, leading to complete disability. Case 1 of my series is a good illustration of this sequence. Immediately on receiving the injury the patient had to rest for a while and then continued to work with difficulty. During the following ten days there developed progressively more severe symptoms of angina pectoris, but he still remained at work. Finally, on the eighteenth day after the accident, coronary thrombosis developed, causing him to remain bedridden for eight weeks. Although the major disablement was delayed eighteen days, there was a continuous train of symptoms between the time of the accident and the coronary occlusion.

To relate an accident or an unusual effort to a subsequent coronary thrombosis or syndrome of angina pectoris one must predicate cardiac symptoms accompanying or immediately following the event to which the cardiac injury is ascribed. If the symptoms are immediately disabling the causal connection is clear. If a lapse of days occurs between the causal event and the complete disablement there must be a continuity of symptoms dating from the event. It is conceivable that an intimal coronary hemorrhage might be caused by severe bodily strain and that it might give rise to no symptoms for several days, until marked obstruction of a coronary artery has taken place. Such a train of events is difficult to prove, and the possibility of its occurrence does not yet warrant its presentation as fact in a court of law.

It has been indicated that the occurrence of coronary thrombosis or the syndrome of angina pectoris after unusual effort gives presumptive evidence of antecedent sclerosis of the coronary arteries. Such arteriosclerotic lesions may give rise to no symptoms and to no cardiac disturbances; they may be nothing but evidence of normal aging. From the point of view of the law, the patient is not diseased nor has he clinical disease. When an unusual strain during work is followed by cardiac disability in the sense outlined, and when this occurs in a person who has been previously well and free from symptoms while at work, it is proper to conclude that the disability was induced by the work and is therefore compensable.

SUMMARY

In fourteen cases coronary occlusion or the syndrome of angina pectoris immediately followed a nonpenetrating injury to the precordium or unusual bodily effort. Eleven additional similar cases have been observed, and further cases have been reported in the literature.

Pathologic studies of several authors suggest the mechanism by which such traumatic lesions of the coronary circulation can be induced.

When a person previously free from symptoms of coronary artery disease has such symptoms after an injury to the chest or unusual physical exertion, the heart disease may be attributed to these external factors. When a person with simple angina pectoris has coronary artery occlusion following such injury or effort the sudden progression of the lesion may be ascribed to these causes. When such a sequence of events occurs in a person gainfully employed while he is at his task, it is proper to conclude that the cardiac disability is compensable, provided the cardiac symptoms accompany or follow immediately on the event to which the cardiac injury is ascribed and provided there is a continuity of symptoms dating from the event to the time of complete disability. Such disability may be delayed by several days or weeks.

1185 Park Avenue.

This Disruption of Medicine.—First physiology abandoned medicine, and in going took largely from medicine its function of studying the normal processes of the body; it also took something more important, for clinical medicine seemed to relax its claim to the use of the experimental method, which it had forged and which physiology, its offspring, now chose as its own chief weapon. Pathology has budded or is budding off, assuming for its part the study of the mechanism of disease, human or otherwise, and in almost all its aspects. This disruption of medicine, as it was originally constituted and as Harvey knew it, may be the inevitable outcome of its growth, may profit physiology, may profit general pathology, may even profit the medical sciences when these are viewed as one whole; but it is a process which can be carried too far, and it then becomes, is becoming, detrimental to the development of the clinical branches of work. It is necessary for medicine, still the parent and still largely possessed of guiding authority, to call a check to this subdivision of her estate.—Lewis, Sir Thomas: Research in Medicine and Other Addresses, London, H. K. Lewis & Co., Ltd., 1939.

LAURENCE BAKER
SAN ANTONIO, TEXAS

In another paper [1] it was pointed out that the introduction of various intracutaneous tests and Huddleson's opsonocytophagic reaction, while providing a new approach to the study of brucellosis, has raised certain confusing problems which have not yet been solved. It seems probable that these tests, together with the agglutination reaction, are of service in indicating whether or not the tissues have been invaded by Brucella at one time or another, in this respect affording information of essentially the same value and limitations as the tuberculin test in suspected tuberculosis or the Wassermann test in syphilis. Doubt has properly been cast on the infallibility of Huddleson's diagnostic criteria, however, by the facts that brucellosis, a common and endemic disease, may be latent or asymptomatic and that the finding of positive tests may thus not indicate active disease but merely coincidental infection of no significance.

The difficulties are further increased by the paucity of physical signs, so that at the present time the diagnosis of brucellosis must rest on indirect laboratory evidence plus a more or less typical symptomatology. It becomes important, therefore, to search for measurable objective abnormalities sufficiently typical and frequent to assist in determining the presence or absence of activity. In a series of patients tested for brucellosis, we have encountered certain morphologic changes in both red and white blood cells so frequently as to warrant a somewhat detailed report.

METHODS AND MATERIALS

Source of clinical material and diagnostic methods were detailed in another communication.[1] Studies of the white blood cells are reported in 271 cases and of the red blood cells in 286 cases. Tests were made in all cases by Foshay's antiserum intracutaneous test,[2] by macroscopic agglutination tests read after forty-eight hours and by Huddleson's opsonocytophagic test (modification of R. M. C. described by Evans.[3]).

Huddleson [4] has stated that a positive cutaneous reaction (brucellergin) with low or absent opsonins indicates active disease. It is generally recognized, however, that cutaneous reactions in any disease are such delicate indicators of bacterial invasion that they may be positive even in asymptomatic disease and hence unreliable as indexes of activity. This objection likewise obtains in Foshay's antiserum test, for this reaction appears to furnish information of the same significance as those tests in which antigens or antigenic derivatives are employed. Frequently patients are encountered who present symptoms compatible with a diagnosis of chronic brucellosis and who yet give only a positive cutaneous reaction. In order to determine whether the hematologic abnormalities are as frequent in this group of cases as in those with more definite evidence of Brucella invasion, we have divided our cases into two series: Group I includes those patients with only a positive antiserum cutaneous reaction, opsonins and agglutinins being absent, while group II includes those patients who, in addition to a positive cutaneous reaction, also had demonstrable agglutinins (1:40 or higher) or opsonins (at least one cell out of twenty-five showing phagocytosis of twenty or more organisms).

Technical Procedures.—All determinations were made with Bureau of Standards glassware. Blood was collected by venipuncture and clotting was prevented by a mixture of potassium and ammonium oxalate (0.05 Gm. of ammonium oxalate and 0.04 Gm. of potassium oxalate to 5 cc. of blood). Counts of the white cells were made in both chambers of a double hemacytometer, the total counts on the two sides checking within 400 cells. Differential counts were done by the two coverslip method and stained with Wright's stain. In every instance 100 cells were classified on each of two separate coverslip preparations; if discrepancies were noted, the slips were discarded and the process was repeated.

* The structure of the white cells in this case was strongly suggestive of infectious mononucleosis; but the heterophile antibody test was negative on two occasions

In the erythrocyte studies, Wintrobe's [5] methods were employed throughout. Red blood cell counts were made from the same pipet on the two sides of a double hemacytometer, the two counts checking within 100,000 cells. Pipets were invariably shaken well in a mechanical shaker. Hemoglobin was determined by the Sahli method with instruments standardized both by the Bureau of Standards and by the Van Slyke method. In all charts dealing with erythrocytes, percentages rather than actual numbers of cases have been used, to permit comparison of our results with the normal range as determined by Wintrobe.[6]

THE LEUKOCYTES

It is generally stated that brucellosis is characterized by leukopenia with relative lymphocytosis. Amoss,[7] however, pointed out that the disease in many instances is actively lymphocytogenic, normal or increased total white blood cell counts often showing a high percentage

of lymphocytes. In our experience acutely and seriously ill patients ordinarily have leukopenia. But in the chronically ill patients in this series leukopenia is not invariable (chart 1). The average total leukocyte count was found to be 7,225 in the group I cases, 7,130 in the group II cases and 7,173 in all cases. Counts above 9,500 not explainable on the basis of obvious complications occurred in thirty instances; of these, only twelve showed a polymorphonuclear leukocytosis while eighteen showed lymphocyte percentages of from 38 to 63 per cent (table 1).

The Lymphocytes.—Evidence of active stimulation of lymphopoietic centers was observed in almost every case. Two hundred and six (76 per cent) of the 271 patients had more than 30 per cent of lymphocytes, and

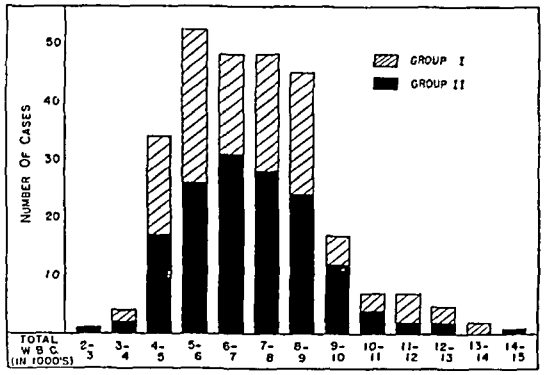

Chart 1.—Total leukocytes.

forty-five patients (16.6 per cent) had more than 50 per cent of lymphocytes (chart 2). Absolute numbers of lymphocytes were likewise increased; 151 of the 271 patients showed more than 2,500 of these cells, and in thirteen cases they numbered more than 5,000 (chart 3). Active lymphocytogenesis was further evidenced by the appearance of immature lymphocytes in the peripheral blood, as studied by the methods of Wiseman.[8] According to Wiseman an absolute value of approximately 100 is the usual maximum of these elements for the normal person. In contrast to this norm, four fifths of our patients showed values higher than 100. Wiseman's studies indicate that the occurrence of such forms constitute a "shift to the left" in the

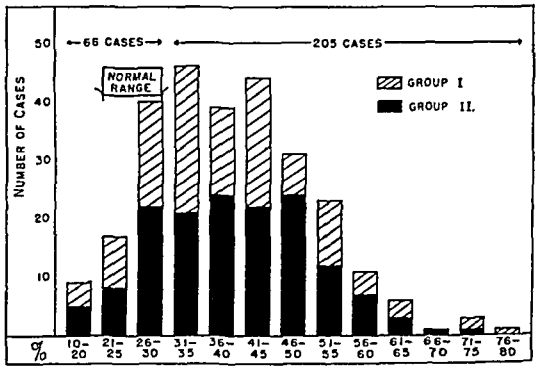

Chart 2.—Percentages of total lymphocytes.

lymphocyte series analogous in import to the well known "shift to the left" in the granulocyte series in the usual Schilling count (chart 4).

Microscopic Appearance of the Lymphocytes.—The mature lymphocytes in our cases frequently showed only a few or even no azurophilic granules. Large lymphocytes were more frequent than small lymphocytes, but this fact, as pointed out by Wiseman, is probably due to fixation and drying. Those cells having relatively large amounts of cytoplasm were not suggestive of the cells of infectious mononucleosis, in that nuclei of

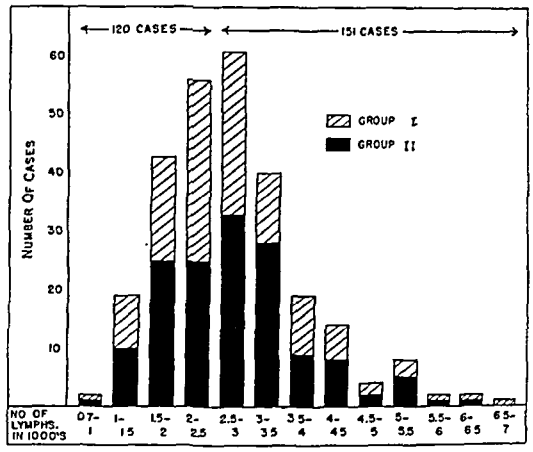

Chart 3.—Distribution of lymphocytes (absolute numbers) by cases.

ameboid shape were not encountered, nor was the cytoplasm of the foamy, light blue appearance characteristic of mononucleosis. Only one exception was noted, and in it the heterophile antibody test was negative on two occasions.

The immature lymphocytes were characterized by the frequent occurrence of nucleoli. The nucleus of these young cells was purplish blue and of fairly even distribution, and the cytoplasm, which contained no granules, was deeply basophilic, approaching true blast

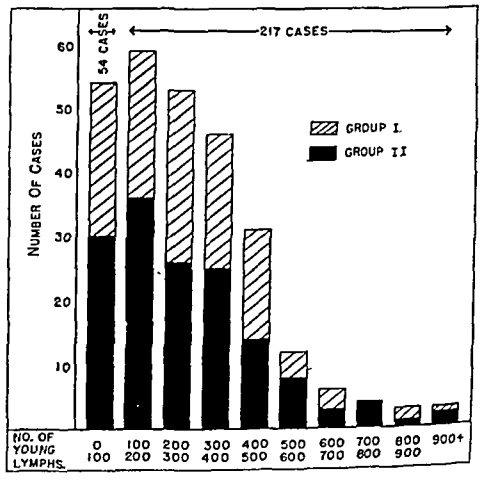

Chart 4.—Young lymphocytes (absolute numbers) by cases.

cells in its affinity for the basic stains. All gradations of basophilia were observed in different cells, but in our data only those cells with deeply basophilic cytoplasm were classified as immature.

Some of the cells, obviously immature because of their cytoplasmic basophilia, differed from those described in that their nucleus was small, round and intensely stained; their chromatin, while densely clumped, was not arranged in orderly fashion. Still other cells, which we classified as young lymphocytes, approached plasma cells in appearance, the chromatin being arranged in typical cart-wheel formation and the nucleus occasionally

8. Wiseman, B. K.: J. Exper. Med. 54:271 (Aug.) 1931.

even being eccentrically placed. We did not classify this type as a plasma cell, however, because the cytoplasm seemed identical in appearance to that of the immature lymphocytes, and the cells were definitely smaller than typical plasma cells.

Plasma Cells.—In slightly more than one third of our cases, cells possessing all the characteristics of plasma cells were observed. When present, they accounted for from 1 to 3 per cent of the total leukocytes. It is not our purpose to discuss whether or not plasma cells belong to the lymphocytic series; in our tables they have not been so classified. If they actually belong in the

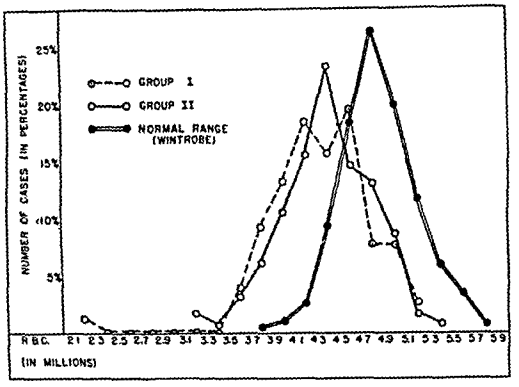

Chart 5.—Red blood cell counts (females).

lymphocytic series, their presence is additional evidence of the lymphocytogenic effect of Brucella infection.

The Monocytes.—In general, the absolute number of monocytes was not increased. Of the 271 cases, 227 (approximately 84 per cent) showed less than 700 monocytes, while forty-four (approximately 16 per cent) showed more than this number. Only seven patients had more than 1,000 monocytes, the maximum being 1,800; only one of these patients was a child, and in all of them tuberculosis had been excluded by appropriate tests.

Structurally there was nothing especially striking about the monocytes. We gained the impression that

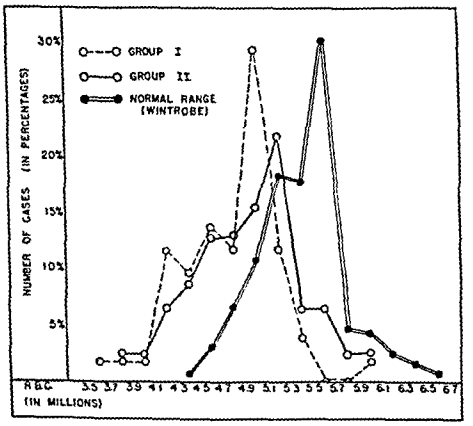

Chart 6.—Red blood cell counts (males).

more than the usual number of these cells showed diffuse, fine, pink granulation and that immature forms, as evidenced by basophilia of the cytoplasm, were more frequent than in normal bloods; but these changes were not definite enough to appear significant.

Monocyte-Lymphocyte Ratio.—Cunningham and Sabin and their associates [9] have stressed the importance of the monocyte-lymphocyte ratio as an index of the state of activity in tuberculosis. Since in many respects the fundamental pathologic changes of tuberculosis and brucellosis are similar, a determination of

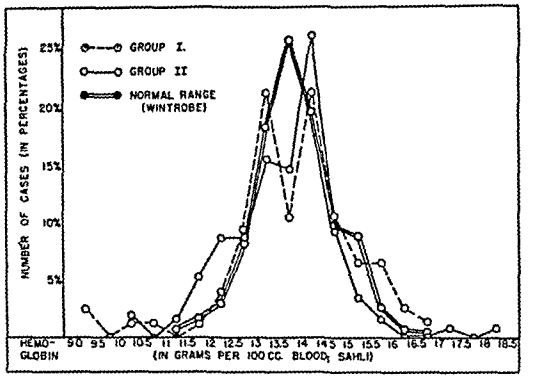

Chart 7.—Hemoglobin (females).

the monocyte-lymphocyte ratio in our cases is of interest. In almost all instances, the observed monocyte-lymphocyte ratio was lower than normal (0.33); it was normal or above in only twenty-seven cases. Extremely low values (0.15 or less) were observed in more than half of the cases. Attempts to relate the monocyte-lymphocyte ratio to state of activity, severity of infection or prognosis must await further observations.

The Granulocytes.—The total number of granulocytes was almost invariably reduced, both in percentages and in absolute numbers. The percentage of "stab" neutrophils was often elevated, but the increase in absolute numbers of these elements was not so striking. The left shift in certain cases is reminiscent of the counts in typhoid; but in our experience the percentage of "stabs" is rarely as high as in typhoid. It would appear from these observations that, in certain instances at least, myelogenic stimuli are present but that peripheral destruction exceeds their production. The question is of practical importance because of the phagocytic role of the polymorphonuclear cells in ridding the body of Brucella.

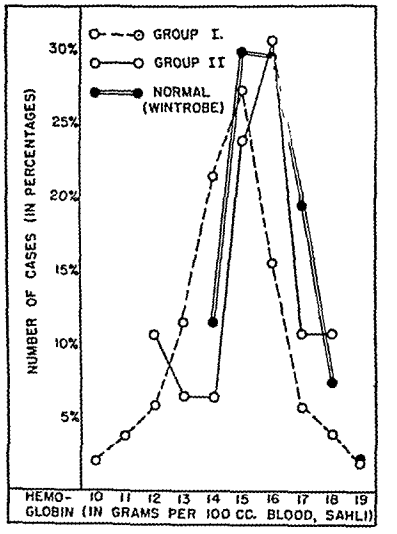

Chart 8.—Hemoglobin (males).

In one tenth of the cases, basophils were present in proportions greater than 1 per cent, the maximal percentage observed being 3. Approximately one fifth of these cases showed eosinophil counts of 5 per cent or more. Even excluding those cases for which there is an obvious explanation of the eosinophilia, the increase

9. Cunningham, R. S.; Sabin, Florence R.; Sugiyama, S., and Kindwall, J. A.: *Bull. Johns Hopkins Hosp.* **37**: 231 (Oct.) 1925.

in these cells is noteworthy. "Stab" eosinophils were frequent, at times equaling the mature forms in number. The significance of these observations is not apparent.

THE ERYTHROCYTES

Total Erythrocyte Counts.—As will be seen from charts 5 and 6, severe grades of anemia were rarely encountered. On the average, the red blood cell counts were approximately a half million lower than normal. Mean values for the various groups are shown in table 2. In the few cases showing severe grades of

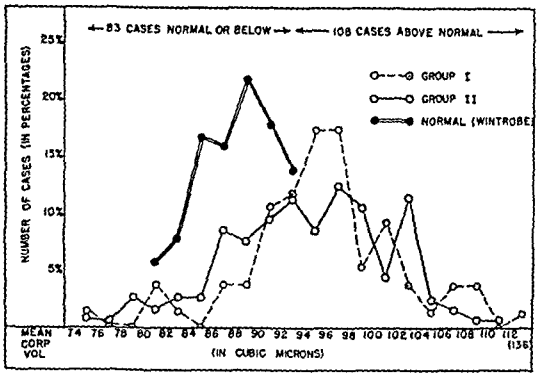

Chart 9.—Mean corpuscular volume (females).

anemia, an explanation of the anemia (menorrhagia, secondary infections, coincidental malaria, inanition and the like) was usually obvious.

Hemoglobin Determinations.—The values for hemoglobin, as determined by the Sahli method and calculated in grams per hundred cubic centimeters of blood, showed curves closely paralleling normal (charts 7 and 8). The average values (table 2) also approximated normal

Volume of Packed Red Blood Cells.—On the average, the volume of the packed red blood cells (obtained by centrifuging in hematocrit tubes and noting the proportion of packed red cells to supernatant plasma) showed a smaller departure from normal than did the total erythrocyte counts (table 2).

TABLE 2.—*Summary of Mean Values*

	Group I Cases	Group II Cases	All Cases	Normal Mean (Wintrobe)
Red blood cells, female	4 32	4 39	4 37	4 85
Red blood cells, male	4 75	4 91	4 82	5 43
Hemoglobin, female	13 72	13.59	13 64	13 90
Hemoglobin, male	14 58	15.46	14 90	15.90
Volume of packed red blood cells, females	41 15	41.16	41 15	41.80
Volume of packed red blood cells, males	43 59	45 72	44 59	47.70
Mean corpuscular volume, females	95 80	94 20	94 80	88 00
Mean corpuscular volume, males	91.90	93 50	92 70	86 50
Mean corpuscular hemoglobin content, females	31 90	31 10	31 40	29 20
Mean corpuscular hemoglobin content, males	30 80	31 60	31 20	29 10
Mean corpuscular hemoglobin concentration, females	33 30	33 00	33 20	33 50
Mean corpuscular hemoglobin concentration, males	32 50	33 90	33 60	34 00

Mean Corpuscular Volume and Hemoglobin Content.—The disproportion between volume of packed red cells and total erythrocyte counts is accounted for by the fact that the average volume of the individual red cell is significantly greater than normal. Similarly, the disparity between total hemoglobin and erythrocyte counts is reflected in hyperchromia of the red blood cells. Charts 9, 10, 11 and 12 show these changes in detail. Definite macrocytosis (charts 9 and 10) was present in more than half of the cases, and the incidence of hyperchromia was likewise striking. In only six cases of apparently uncomplicated brucellosis were microcytosis and hypochromia observed.

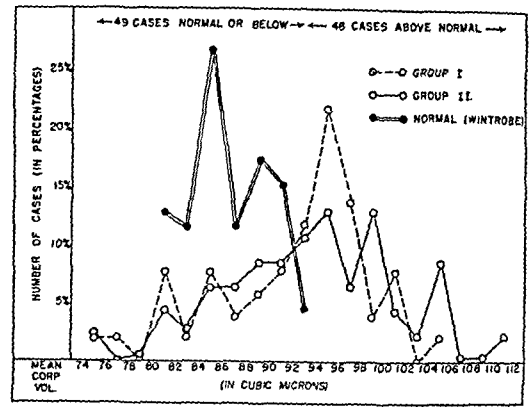

Chart 10.—Mean corpuscular volume (males).

As a check on the accuracy of our determinations of average erythrocyte volume, measurements of the diameters of red blood cells by the method of Price-Jones were made in twenty-three of these cases. By this method also a distinct macrocytosis is apparent (chart 13).

Mean Corpuscular Hemoglobin Concentration.—Bethell [10] has called attention to the fact that, if the plasma proteins are low, osmotic relationships between red cells and plasma are disturbed, with resultant swelling (relative macrocytosis) of the erythrocytes. Since the hemoglobin content of the cell remains constant, the swelling of the cell results in its being less saturated with hemoglobin than usual. Such a condition results in the triad of macrocytosis (cell volume greater than

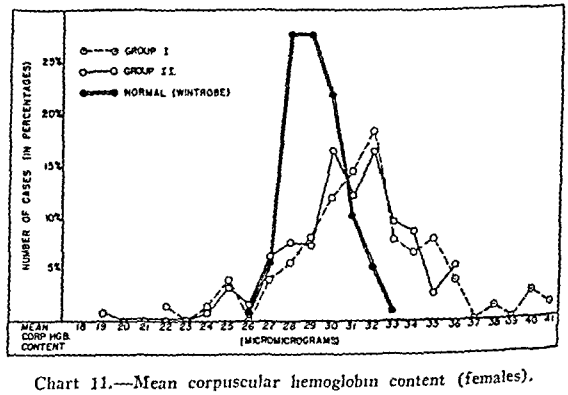

Chart 11.—Mean corpuscular hemoglobin content (females).

95 cubic microns), normal mean corpuscular hemoglobin content (from 28 to 31 micromicrograms), and decreased mean corpuscular hemoglobin concentration (less than 32 per cent).

Our cases were therefore analyzed to determine how frequently this triad occurred. Charts 14 and 15 show the hemoglobin concentrations of all patients studied. It will be noted that the hemoglobin concentration is low in a fairly large percentage of cases (sixty-eight cases). But these data include forty-five cases of definite hypochromia, most of them presenting complications sufficient to account for the low hemoglobin

10 Bethell, F. H., and Rottschaefer, Gerald: Univ. Hosp. Bull., Ann Arbor 2:65 (Nov.) 1936.

content. Excluding these and two cases of pregnancy, there remain only twenty-one cases (7.3 per cent) in which the possibility exists that the observed macrocytosis was due, partly at least, to a circulatory phenomenon.

In contrast to this small number of patients in whom the macrocytosis was apparently merely a physical phenomenon, it is impressive to note the large number of cases in which the hemoglobin concentration of macrocytes was normal or even high. The conclusion seems justified that the observed macrocytosis is due not merely to physical alteration of osmotic relationships but to defects of maturation.

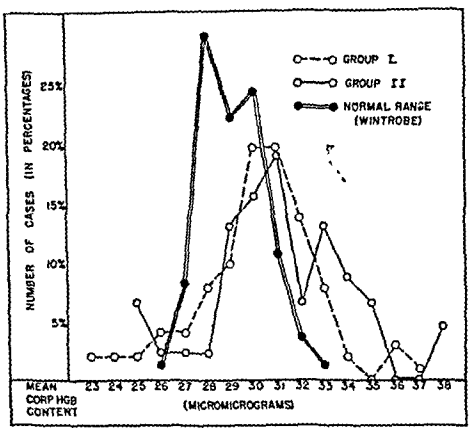

Chart 12.—Mean corpuscular hemoglobin content (males).

Microscopic Appearance of Erythrocytes.—Variations in size and shape of the erythrocytes were minimal. In general, the cells were all larger than normal and their hemoglobin content was likewise uniformly increased. Hypochromia and microcytosis were distinctly rare. In a very few instances pencil-shaped cells were observed. Nucleated red blood cells were infrequent. In two or three cases the inclusion of red blood cells in monocytes was observed. Polychromatophilia of slight degree was present in approximately 10 per cent of the cases.

Reticulocytes.—Reticulocyte counts were done in twenty-two of the cases reported in this series. The values ranged from 0.3 to 3.3 per cent, with mean values of approximately 1 per cent.

TABLE 3.—*Sedimentation Rates of Erythrocytes*

Millimeters per Hour	Group I Cases		Group II Cases	
	Male	Female	Male	Female
1-5	8	1	15	3
6-9	10	13	4	15
10-15	10	16	11	22
16-25	12	23	9	32
26-35	5	10	4	23
36-45	2	6	1	8
46-55	3	5	3	9
56-65	2	1	0	3

Coagulation.—In approximately one third of these cases, clotting was slow and incomplete. Free cells were often present even after the blood had stood overnight in the ice box. Normal retraction of the clot was rare; often there was no retraction at all. The coagulation defects do not seem to be related to decrease in blood platelets, for these elements are grossly normal in number and appearance in the stained preparations.

Sedimentation Rate of Erythrocytes.—Moderate acceleration of sedimentation rates (above Wintrobe's normal of 9 mm. for males and 15 mm. for females) occurred in slightly more than one third of these cases.

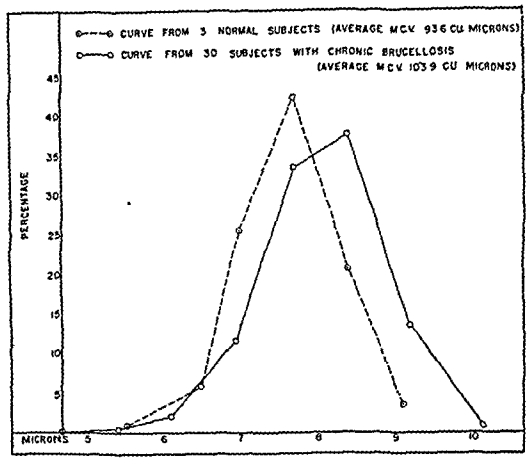

Chart 13.—Price Jones curves in chronic brucellosis.

Very slow rates were not uncommon. Excessively fast rates were usually explainable on the basis of complications, such as arthritis or effusions (table 3).

Gastric Analysis.—Gastric analysis was done in ten cases in which there were macrocytosis and hyperchromia. Our procedure was to aspirate the fasting contents and then administer 50 cc. of 7 per cent alcohol and 0.4 mg. of histamine, specimens being withdrawn at fifteen minute intervals.

In nine of the ten cases there was no free hydrochloric acid in the fasting specimens. All of them, however, showed free acid after histamine. Values

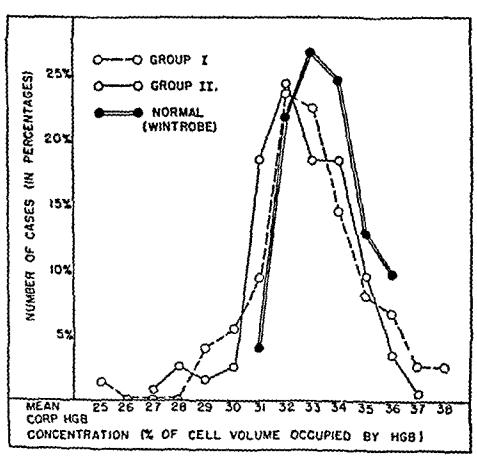

Chart 14.—Mean corpuscular hemoglobin concentration (females).

were definitely low in five cases, in the lower limits of normal in two cases and within the usual range of normal in three cases. Neither complete histamine anacidity nor, on the other hand, excessively high acidity was encountered.

Van den Bergh Tests.—The van den Bergh test was performed on 142 untreated patients. Of these, eighty-seven (61 per cent) showed bilirubin values of less than 0.5 mg. per hundred cubic centimeters of blood, while fifty-five (39 per cent) showed higher values. In the latter group, most of the values were less than 1 mg., the highest being 1.8 mg. The reaction was of the delayed direct type, the color change occurring after

thirty seconds and reaching its maximal intensity before the addition of alcohol and ammonium sulfate.

Evidence of Damage to the Liver.—It has been recognized previously that portal cirrhosis of the liver is often associated with macrocytosis. Wintrobe [11] has summarized the literature on the subject, and his description of the blood changes in diseases of the liver parallels our observations on the blood in these cases: "The anemia . . . is rarely severe. The macrocytosis affects the great majority of the red corpuscles, which show relatively little variation in shape or size. The lack of variation in the size of the corpuscles, however, does not distinguish the condition from pernicious anemia, for the distribution curves of the diameters of the red corpuscles are like those in cases of pernicious anemia with similar grades of anemia. Nucleated red corpuscles are uncommon and the fragility of the erythrocytes is normal." It is very unlikely that the cases which are included in our series represent the accidental association of pernicious anemia with brucellosis, for in the first place they are too numerous, and in the second place histamine anacidity has not occurred in those cases in which the gastric contents have been examined

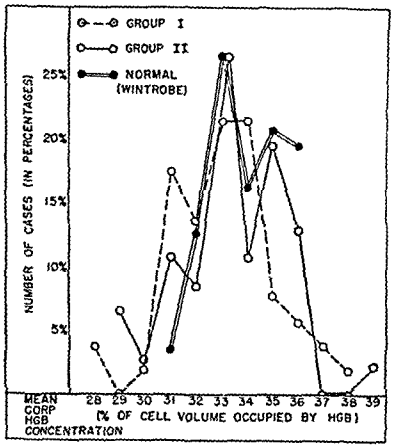

Chart 15.—Mean corpuscular hemoglobin concentration (males)

The striking parallelism between our observations and those cited by Wintrobe as occurring in hepatic disease makes reasonable the conclusion that these changes in all probability are due to anatomic or functional derangement of the liver. Contributory evidence for this idea is held in the facts that (1) low grade jaundice as measured by the van den Bergh reaction is not uncommon, (2) this reaction is of the delayed direct type, which ordinarily is associated with structural damage to liver parenchyma, and (3) the liver is, in our experience and that of others, more commonly enlarged in this condition than is the spleen.

SUMMARY

Structural studies of the blood were made in almost 300 patients with evidence of Brucella invasion. Normal leukocyte counts occurred in one half, leukopenia in one third and leukocytosis in one sixth of the cases. Active lymphocytosis was the most striking feature encountered and was evidenced by an increase in both percentage values and absolute numbers of lymphocytes and by unusually high numbers of immature lymphocytes (a lymphocytic "shift to the left"). Plasma cells were frequent. Monocytes in general were not increased in number, and the monocyte-lymphocyte ratio was almost invariably low. Many cases showed a moderate increase in percentage of "stab" neutrophils, but the total number of neutrophils was usually reduced. In one fifth of the cases there was moderate eosinophilia, often with immature forms.

Mild anemia of the macrocytic, hyperchromic type was frequent. Evidence was obtained that these changes are due to maturation defects, probably the result of damage to the liver.

Coagulation of the blood was slow and often incomplete. Clot retraction was also imperfect. The sedimentation rate was usually not extremely high except when complications, such as arthritis, were present.

These abnormalities of the blood were observed so consistently that they appear to represent a fundamental part of the disease with which these patients are suffering. So far as we are aware, they are duplicated in their entirety by no other known disease. It would seem, therefore, that the regularity with which they occurred in this group of patients is confirmatory evidence of the specificity of the tests on which the diagnosis of brucellosis was made.

Further analysis of our data indicates that these blood changes occur as often in patients with only a positive cutaneous reaction as in those who also show agglutinins and opsonins. Since these abnormalities seem to be a specific effect of Brucella invasion, their equal incidence in the two groups of patients indicates that, in many instances, a positive antiserum cutaneous reaction may be the sole evidence of brucellosis.

It is our main purpose in the present article to discuss treatment of the bleeding tendency so often seen in patients suffering from disease of the biliary tract. Bleeding from mucous surfaces often occurs spontaneously in these patients, but the greatest danger is from bleeding at operation or from the wound after operation.

Through the work of several laboratories [1] it has been shown that a newly discovered vitamin, vitamin K,

plays an important part in prothrombin formation in the body. Patients with obstructive jaundice or with biliary fistulas, having no bile in the intestine, have difficulty in absorbing such fat-soluble materials. Without adequate absorption of vitamin K they suffer from faulty formation of prothrombin, and for this reason a tendency to bleed develops.

The therapeutic use of vitamin K in the treatment of jaundiced bleeders was first reported by Warner, Brinkhous and Smith [2] and almost simultaneously by Butt, Snell and Osterberg.[3] Additional cases were reported almost at once by Dam and Glavind.[4] All these reports have indicated that dramatic relief from the bleeding tendency is obtained in most cases by the administration of vitamin K. Further details of the literature on this vitamin may be obtained from the articles just cited.

BLEEDING IN OBSTRUCTIVE JAUNDICE: REPORT OF CASE

E. W., a white woman aged 53, who entered Mercy Hospital April 20, 1938, because of pruritus and jaundice, for the past two years had had periodic attacks of pain in the right upper quadrant of the abdomen. The attacks lasted from one hour to several days. Early in February they increased in severity and were accompanied by lassitude and weakness. Jaundice made its appearance at this time, but the patient refused hospital treatment until the pruritus had become intolerable.

She was well developed and well nourished. The skin showed marked jaundice and much excoriation because of the pruritus. There were considerable rigidity and tenderness in the right upper quadrant, but the gallbladder could not be felt. The temperature, pulse rate and respiratory rate were within normal limits. The stools were clay colored and the urine deep yellow. The coagulation time was six minutes by the capillary tube method.

At operation, April 22, a number of stones were removed from the gallbladder and one large stone was removed from the common bile duct. A drainage tube was placed in the gallbladder and another in the common bile duct.

After operation the patient showed no untoward symptoms for several days. The temperature remained at about 37 C. (98.6 F.). April 26 bile ceased to drain and some blood dripped from the tube. Irrigation of the tube was attempted but was discontinued because of pain. On the following day the dressings were found to be saturated with blood. The patient vomited 300 cc. of fluid which contained bright red blood. The stools were tarry black. Bleeding continued on the following day and the jaundice, which had been subsiding, began to increase, probably because of obstruction by blood clots. April 29 an attempt was made to give an enema, but before much fluid had been injected the patient expelled 1,000 cc. of reddish black fluid, obviously blood.

A sample of blood drawn at this time showed deep jaundice of the plasma (van den Bergh test, 17 mg. per hundred cubic centimeters). The coagulation time was thirteen minutes by the capillary tube method. The bleeding time (Duke's method) was greatly prolonged, the patient continuing to bleed for more than six hours from a simple stab wound. The red cell count, previously normal, had now fallen to 2,000,000. A transfusion of 300 cc. of blood was given April 29 and another April 30. These transfusions seemed to have little effect, for oozing from the operative wound continued.

At this stage, analyses for prothrombin carried out for the first time showed the plasma prothrombin content to be 8 per cent of normal, a result considered adequate to explain the bleeding. April 30 and May 1 vitamin K emulsified in 30 cc. of 2 per cent sodium taurocholate was given by mouth. Each dose contained the vitamin which had been extracted [4a] from 200 Gm. of dry alfalfa meal. Bleeding from the operative wound ceased within twenty-four hours of the onset of treatment. The treatment itself produced some nausea; hence the vitamin was given in capsule form on the following two days. May 3, after three days of treatment, the plasma prothrombin content had risen to 69 per cent of normal from the original 8 per cent. The bleeding time (Ivy's [5] method) was now six minutes. May 3 and 4 the vitamin, given in emulsion form in half the original dose, produced no nausea. During the following three days no vitamin K was given and May 7 the dressings again showed blood. Blood drawn for analyses showed that the plasma prothrombin content had fallen to 47 per cent, a level which we have come to consider in the upper part of the danger zone. From May 9 to 18 the patient received vitamin K emulsion equivalent to 100 Gm. of alfalfa meal daily. The bloody drainage ceased on May 10, and the plasma prothrombin content on May 17 was found to be 71 per cent of normal.

The jaundice increased for a few days after removal of the drain on May 1 but thereafter it subsided and on May 12 the van den Bergh test showed that the plasma bilirubin content had fallen to 4.1 mg. per hundred cubic centimeters. May 18 the jaundice had completely subsided and vitamin K therapy was discontinued. The remainder of the patient's stay in the hospital was entirely uneventful, except for a transient period of vomiting. The patient left the hospital June 5 and when seen August 23 had remained free from symptoms.

This case illustrates postoperative bleeding in a patient with chronic biliary obstruction. There was no serious bleeding at the time of operation, but four days after operation blood began to ooze at the operative site and this bleeding continued despite two transfusions. The plasma prothrombin concentration at that time was 8 per cent of normal. We have noted in a number of cases that when the plasma prothrombin level is low prior to operation one may anticipate a further fall after operation. This fall is presumably due to the utilization of prothrombin in forming fibrinous exudate at the operative site. The level at which bleeding actually occurs is variable, and the actual onset of bleeding is often precipitated by the operation itself or even by minor traumatic factors. Rarely does bleeding occur until the prothrombin has been reduced at least to 50 per cent of normal. Occasionally a level of 20 per cent will be tolerated without hemorrhage, but patients below the 50 per cent level are definitely in the danger zone.[5a]

Relief from bleeding in this case occurred within twenty-four hours after the institution of vitamin K therapy. This is in accord with previous experience [6] that the plasma prothrombin level rises rapidly out of the danger zone when vitamin K is absorbed in adequate amounts. At the end of three days of treatment the prothrombin level had risen to 69 per cent of normal, whereas it had been 8 per cent of normal. This case also illustrates the point that treatment should not be relaxed too early, for when it was discontinued the prothrombin level fell to 47 per cent within three days and bleeding began again. On resumption of therapy, bleeding again ceased and the prothrombin level rose to 71 per cent. One cannot urge too strongly that

therapy be continued at least as long as bile continues to drain at the operative site. This use of the vitamin should be extended to include the preoperative period. Had this particular patient been given vitamin for several days prior to operation, there is little doubt that excessive bleeding would have been prevented altogether.

PROTHROMBIN VALUES IN OTHER CONDITIONS

The accompanying table shows prothrombin values in a number of clinical conditions In three cases of thrombopenia the plasma prothrombin values were within normal limits. These cases throw doubt on the view, occasionally cited,[7] that platelets are the source of prothrombin.

In three cases of hemophilia the prothrombin values were normal. In case 4 two weeks treatment with vitamin K produced no change in the prothrombin or the clotting time (forty-five to seventy-five minutes). This is in accord with the experience of Dam and Glavind.[4]

Miscellaneous Plasma Prothrombin Values

Case No	Sex	Age (Yr.)	Diagnosis	Prothrombin, %
1	♀	13	Thrombopenic purpura	90
2	♂	0.5	Thrombopenic purpura	79
3	♂	31	Persistent thrombopenia, nonsymptomatic	100
4	♂	25	Hemophilia	96
5	♂	11	Hemophilia	86
6	♂	44	Hemophilia	92
7	♂	6	Acute leukemia	66
8	♂	46	Acute leukemia	82
9	♂	7	Acute leukemia	86
10	♂	55	Laennec's cirrhosis; primary carcinoma of liver (autopsy)	79
11	♂	55	Laennec's cirrhosis (clinical)	42
12	♂	24	Laennec's cirrhosis (autopsy)	72
13	♂	29	Laennec's cirrhosis (clinical)	66
14	♂	25	Laennec's cirrhosis (autopsy)	30
15	♂	23	Laennec's cirrhosis, slight; "Banti's disease" (laparotomy)	66
16	♀	50	Syphilitic "Banti's disease" (clinical)	65

In three cases of acute leukemia there was moderate reduction in the prothrombin level.

In six cases in which the diagnosis of Laennec's cirrhosis of the liver had been made there was a reduction in the prothrombin level. In two of these the value was definitely in the danger zone, but in neither did we observe areas of bruising or evidence of bleeding from mucous surfaces, such as one sometimes sees in patients with this disease. Patient 11 was treated for two weeks with vitamin K, but the prothrombin level remained constant at about 40 per cent. Patient 16, with a clinical diagnosis of syphilitic Banti's disease, was treated in a similar manner but without effect on the prothrombin concentration. Such results indicate that the lowering of the prothrombin concentration is not the result of a deficiency in vitamin K.

COMMENT

There is as yet no proof that vitamin K is a component of the prothrombin molecule. It may be, instead, in some way essential to proper function of the tissues concerned in the manufacture of prothrombin.

Work from this laboratory indicates that the liver is vitally concerned in the process of manufacturing prothrombin, for the plasma prothrombin level falls when the liver is partially excised [8] or when it is injured by chloroform poisoning.[9] It seems probable that the lowering of the prothrombin level in cases of cirrhosis is due mainly to defective hepatic function, which is not the result of deficiency in the supply of vitamin K This view is in accord with the fact, already reported,[4a] that patients with disease of the biliary tract may respond poorly to vitamin K if the liver is badly damaged (i. e. by obstructive biliary cirrhosis or by extensive growth of a neoplasm within the liver). It is now clear that prothrombin formation can be interrupted either by a reduction of the supply of vitamin K or by interference with the integrity of the liver. The vitamin is of therapeutic value in the former case.

The technic for titration of prothrombin is still somewhat too involved for general use and we have had little success in predicting bleeding by the use of tests of the bleeding time and clotting time. Many patients have normal values by these tests, and yet persistent bleeding develops. Unless prothrombin analyses are made, it is advisable to give the vitamin in a routine manner for several days to all patients with biliary disease both before operation and during the crucial postoperative period.[10] The vitamin appears to be entirely harmless, for we have given it to animals in doses many times as great as the amount recommended for therapeutic use.

It has been suggested that vitamin D may be useful in the treatment of the bleeding tendency of patients with disease of the biliary tract. Being fat soluble, this vitamin too is absorbed with difficulty when bile is absent from the intestine.[12] McNealy, Shapiro and Melnick [13] analyzed a large series of cases of disease of the biliary tract both with and without supplements of this vitamin. Their conclusions, based partly on clinical evidence and partly on tests of bleeding time, indicated a beneficial effect. A little later Boys [14] reached the same conclusion. Wigodsky and Ivy [15] have recently analyzed a vitamin K preparation and found it to contain so little vitamin D that its activity in such patients cannot be ascribed to the latter. It is possible that in human beings, when the disease is complicated by infection, a deficiency in vitamin D may contribute to the difficulty in forming prothrombin However, our own experiments on dogs with sterile biliary fistulas [16] failed to show that vitamin D has any effect in raising the prothrombin level. In the aforementioned cases bile or bile salt was fed along with

vitamin D. Since the diet normally contains small quantities of vitamin K, it is possible that the bile salt given permitted enough absorption of this vitamin to raise the prothrombin level out of the bleeding zone. It is to be hoped that studies of human beings will be repeated with the plasma prothrombin level as a control on the procedure.

CONCLUSIONS

Our case illustrates postoperative bleeding in a patient with obstructive jaundice. Such bleeding is due to profound reduction in the plasma prothrombin level. When the patient was treated with vitamin K, the prothrombin level rose and bleeding ceased.

Patients with thrombopenic purpura and patients with hemophilia have normal prothrombin values, and evidence indicates that such patients obtain no relief from administration of vitamin K.

In three cases of acute leukemia the prothrombin level was found to be slightly reduced.

In cases of Laënnec's cirrhosis the prothrombin level may be markedly reduced, but evidence indicates that the reduction is due to defective hepatic function, which is not the result of deficiency in vitamin K.[17]

ACUTE INTERSTITIAL PNEUMONITIS: A NEW DISEASE ENTITY

D. F. SMILEY, M.D., E. C. SHOWACRE, M.D.; W. F. LEE, M.D., AND H. W. FERRIS, M.D.
ITHACA, N. Y.

The Cornell University Infirmary receives practically all seriously ill patients from the student body. Minor ailments, such as common colds without fever, are taken care of at the medical adviser's office or in the offices of practicing physicians of the town.

The infirmary records of the twenty years from 1917 to 1937 reveal that (1) the many cases of "cold and fever" occurred irregularly through every year but always reached their peak sometime in December, January, February or March, (2) pandemic influenza occurred in 1918-1919 and 1919-1920 only, (3) interpandemic influenza occurred in definite outbreaks in 1925-1926, 1927-1928, 1931-1932 and 1936-1937

TABLE 1.—*Diseases of the Respiratory Tract from 1925 to 1937*

Year	Student Registration	Cases of Uncomplicated Interpandemic Influenza	Cases of Interpandemic Influenza Complicated by Pneumonia	Cases of Pneumonia Unrelated to Influenza
1925-1926	5,132	644	4	4
1927-1928	5,205	437	3	11
1931-1932	5,916	639	3	13
1936-1937	6,177	824	4	8

(table 1) and (4) from eight to sixteen cases of pneumonia occurred through each nine month college year (table 1).

In October 1937 there began to appear a type of infection of the respiratory tract different from anything that we had seen previously. It did not belong to any of the four categories listed. It did not attack large numbers, as interpandemic influenza had usually done, and it was not accompanied in the majority of cases by the bone ache and backache of typical influenza; it was apparently a new acute disease of the respiratory tract having as its cardinal feature specific lesions in the lungs inaudible to the stethoscope but definite in the roentgenogram of the chest. To this disease we have applied the term acute interstitial pneumonitis.

TABLE 2.—*Diseases of the Respiratory Tract from 1937 to 1939*

Year	Student Registration	Cases of Uncomplicated Interpandemic Influenza	Cases of Interpandemic Influenza Complicated by Pneumonia	Cases of Pneumonitis	Cases of Pneumonia Unrelated to Influenza
1937-1938	6,115	129	1	39	8
1938 to Jan. 24, 1939	6,569	41	0	27	4

Since October 1937, in no month when the infirmary was open have we failed to have cases of pneumonitis. There have been eighty-six cases as shown by definite radiographic evidence (table 2).

RADIOGRAPHIC EVIDENCE

Several of the patients had roentgenograms taken before definite evidence was visible on the film and were then observed almost daily as the pathologic change was developing in the lungs. Others were rechecked at regular intervals during the entire period of their illness. A review of the roentgenograms leads to the conclusion that (*a*) definite x-ray evidence may not appear until from thirty-six to forty-eight hours after the clinical onset, (*b*) the infection spreads from the hilus outward, following the bronchial and vascular tree, as do many other pulmonary infections, and (*c*) the cases can be roughly divided according to the radiographic evidence into three groups.

The onset has been marked by increased density in the hilar shadows, with a fan-shaped localized accentuation of and a numerical increase in the linear pulmonic markings extending from the hilus into the adjacent lung field. This extension is down into the base in the majority of the cases; it may be lateral or, not infrequently, into the first and second interspaces. In one group of cases, those of milder involvement, there then appeared over this area a diffuse even increase in density, which was not sufficient, however, to eliminate the linear markings and suggested an intense congestion rather than a true consolidation of lung tissue. The visible changes did not usually extend to the margin of the lung, and they cleared rather rapidly, ordinarily in from one to two weeks (fig. 1).

In a second group of cases, of more serious involvement, the infiltration in the fan extended more frequently to the periphery of the lung, with irregular areas of markedly increased density suggestive of lobular involvement and more typical of definite bronchopneumonia. Resolution was correspondingly slower than in the first group (figs. 2 and 3).

In about 5 per cent of the cases the involvement was severe. The development was similar to that in the preceding groups except that, in addition to the original focus, there was a diffuse spread throughout the remainder of the lung with partial or complete involvement of the other lung. This additional involvement was characterized by a generalized swelling of the pulmonic markings with a light mottling somewhat

17. Since this article was written, vitamin K has been placed on the market by Abbott Laboratories, North Chicago, Ill. The vitamin K preparations used in our own work were prepared partly by ourselves and partly on an experimental basis by the Upjohn Company of Kalamazoo, Mich.

From Cornell University Infirmary.

similar to that of pulmonary edema or intense passive congestion and additional irregular blotchy areas of very lightly increased density. We believe the underlying pathologic change in this type of case to be a definite interstitial inflammation. In this group there was a decided tendency to some involvement of the interlobar pleura and, in one case, of the parietal pleura. Clearing of the lung fields was slow, taking from one to two and one-half months (figs. 4, 5 and 6).

FIG 1 (case 1).—A typical rounded fan present in the cases of mild involvement and frequently in the early stages when the disease is severe, showing the intensified lineal markings through a hazy background.

COURSE

The onset of the disease is usually not sudden but is ushered in by a period of weakness, malaise and slight fever lasting for two or three days. The temperature gradually mounts, and the patient begins to complain of cough, pains in the chest or sore throat or a combination of these symptoms. (In some cases, however, the onset has been sudden, as in pneumonia.) At this stage there are usually signs of pharyngitis or a cough and a temperature of from 100 to 102 F., but stethoscopic examination of the chest gives no evidence of consolidation and there is little or no sputum. There may be a few fine rales. The radiographic evidence at this stage is usually that of group 1, and in many cases the disease recedes from this point (fig. 1).

As the disease progresses, as it does in cases of group 2, the temperature rises to 103 or 104 F., not infrequently exhibiting the peculiarity of being up in the morning and down in the evening. The patient feels quite ill at this stage, not infrequently complains of tightness in the chest and pain on coughing and sometimes shows the flushed cheeks so often seen with pneumonia. Stethoscopic examination of the chest still reveals no pleurisy or consolidation; there may be a few fine rales, and sputum is entirely lacking or scanty and has been in none of our cases either of the "rusty" or of the "cherry juice" type. Roentgenograms of the chest at this period show the fan-shaped area of increased density, generally extending to the periphery of the lung (fig. 3).

FIG. 2 (case 2).—A typical rounded basal fan on the second day of illness and the forerunner of a more severe infection (see fig. 3).

In our third group of cases, the onset and development of the disease was similar to that in group 2 except that there was a characteristic sudden jump in the temperature and evidences of toxicity, indicating a sudden and pronounced spread of the infection. The febrile period was more prolonged and more severe. Moist rales were invariably present, but the sputum was still scanty in proportion to what one might expect from the rales. The toxicity of the disease was severe, and the prognosis in each case for a number of days was grave. We believe that these cases are similar to those described by Dr. Hobart Reimann.[1]

The leukocyte counts have shown mild leukocytosis, the commonest count early in the disease being about 8,500 and running later up to 14,000 or 16,000. In one instance late in the disease there was a leukocyte count of 22,000. The percentages of polymorphonuclears has been in most instances between 63 and 75. In only one instance did it reach 88.

The pneumonitis terminates by lysis; there is no spectacular crisis. The patient was usually hospitalized ten days, though one of the four, with severe extension of the process to both lungs, required seventy-six days. Sixty-one of the eighty-six were hospitalized for a period not exceeding fourteen days. Complications are apparently rare, there having been no bronchiectasis, no organization of exudate and no abscess in our first eighty-six cases of the disease. There have, however, been evidences of mild pleuritic involvement in those of severe involvement. In the cases of rather rapid recovery in which the pulmonary lesions have previously been lacking, it is not unusual to find, after the patient has had a normal temperature for three or four days and been discharged from the infirmary, many coarse rales over the areas shown by roentgenogram to be involved. These rales may be present for as long as two weeks after the termination of treatment in bed. Though the course of the disease is comparatively short in the cases of mild involvement, it has not infrequently caused the loss of from 16 to 18 pounds (7 to 8 Kg.) in otherwise healthy young college students, and several patients have found themselves so weak at the termination of the disease that they have had to ask leave of absence for the remainder of the term to recuperate. That some students can take this disease in their stride is evidenced, however, by the fact that one of our football players had a typical attack in October 1938, recovered completely and went on to participate successfully in a hard schedule of intercollegiate football.

FIG. 3 (case 2).—Appearance on the eighth day of illness. The area of density has extended to the periphery of the lung and is considerably widened. This represents the maximum spread of the process in this case.

EPIDEMIOLOGY AND ETIOLOGY

Among the eighty-six patients so far observed, there have been six instances of two from the same house, one instance of five from the same house and one

1. Reimann, Hobart A.: An Acute Infection of the Respiratory Tract with Atypical Pneumonia, J. A. M. A. **111**: 2377-2384 (Dec. 24) 1938.

instance of four from the same house. In the clusters of four and five cases, the original patient was ill and coughing about the fraternity house for several days before he went to the infirmary; the other patients followed at intervals of from five to fourteen days in one instance and from thirteen to fourteen days in the other. The other patients admitted having gone into the room of the original patient and having talked with him, thinking he "just had a cough."

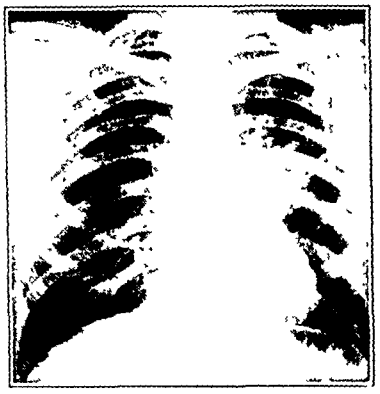

Fig. 4 (case 3).—Initial rounded fan on the third day of illness

In the absence of cough, the infectiousness of the disease may not be very great, since we had in the series one instance in which, under the crowded conditions of a house party week-end, two students slept in the same bed with another student ill with pneumonitis (but not coughing) and remained well. A student who sat next to one with pneumonitis (who was coughing) in his economics class came down with the same disease twelve days later.

As a result of our limited experience, we feel that this disease is more infectious than pneumonia, and we now, as a routine, hospitalize and isolate all our patients, permitting no visitors.

In the absence of sputum, cough swabs have been obtained by tickling the pharynx. Cultures of material from these swabs and of sputum have frequently been reported as showing mixed Streptococcus viridans and Staphylococcus aureus. In mouse tests of the sputum at the Tompkins County laboratory, the mice have but rarely succumbed, but when they have, pneumococci have usually been found. Material sent to the New York State Health Department laboratory has led to occasional reports of the higher types of pneumococci, e. g. type VIII, types XV and XVIII and type XI. On the basis of evidence accumulated to date, no definite statement can be made as to cause, but a virus would seem more probable than bacteria.

Fig. 5 (case 3).—Maximum spread on the ninth day of illness. Note the extension of the original fan and the diffuse mottling of the remainder of the originally involved lung and also of the other lung

COMMENT

The question may well be asked Why is this disease not simply atypical pneumococcic pneumonia? We feel that it is not for the following reasons:

1. The areas of density shown in the roentgenograms are not lobar and are less dense than in the case of lobar pneumonia. The radiographic evidence in the majority of cases does not conform with that usually found in cases of bronchopneumonia. 2. The fever is intermittent rather than continuous, as in pneumonia. 3. There is milder leukocytosis and a smaller rise in the polymorphonuclear count than is the rule in pneumonia. 4. Severe sweating is much more common than in pneumonia. 5. The disease appears to be more communicable than pneumonia usually is. 6. The respiratory rate is not as high as that usually found with pneumonia. 7. There has been much less sputum and no "rusty" sputum or "cherry juice" sputum in our cases. 8. There is much less prostration than is the rule in pneumonia. 9. The number of cases and the time of year they have occurred are both entirely out of line with any of our previous records of pneumonia. 10. Careful bacteriologic examination has failed to show pneumococci consistently in the sputum, while rapid isolation and typing of pneumococci in cases definitely of pneumonia is our common experience.

Is acute interstitial pneumonitis a new disease? A checking of the available literature does not give us a definite answer to this question. In only four published works do we find reference to outbreaks of disease probably identical with or closely allied to this disease:

1. According to the records of the medical department of the United States army in the World War:[2]

> Certain cases of average severity, however, showed on physical examination persistent rales at either base. At Fort Sam Houston, Texas, 25 per cent of 1,000 cases of uncomplicated influenza gave this finding. There was no other evidence clinically of anything resembling pneumonia; however, x-ray plates showed local areas of increased density corresponding to the physical signs in practically all of this group. This finding is probably to be interpreted as an early or slight example of the lesion described from Walter Reed General Hospital as "hemorrhagic pneumonitis."

Fig. 6 (case 4).—Diffuse mottling with irregular blotchy areas of lightly increased density, typical of the severe form, on the eleventh day of illness. This may be present for two or three weeks before it begins to recede

2. Major Albert Bowen[3] recorded an epidemic of "acute influenza pneumonitis" occurring in United States troops stationed in Hawaii from 1931 to 1934 and described the radiographic evidence as follows:

> Influenza pneumonitis involves only a portion of a lobe, usually basal, though it has been seen in the upper lobes and involving more than one lobe without increase in symptoms. It extends outward from the hilus well into the parenchyma, occasionally reaching the periphery. The roentgen appearance is

2. United States History of the World War, Washington, D. C. Government Printing Office, 1928, vol. IX, Section on Roentgenology, p. 153.

3. Bowen, Albert: Acute Influenza Pneumonitis, Am. J. Roentgenol. 34: 168-174 (Aug.) 1935.

that of a confluent mottled fan or rounded area, usually of homogeneous moderate density in the central portion, with the borders fading into the normal lung. It has the appearance of an exudative alveolar infiltration and is usually more localized and of more even density than the bronchopneumonias of childhood or than those which complicate adult diseases.

3. Dr. William H. Allen [4] reported sixty-eight cases of "acute pneumonitis" in the wards of the Station Hospital, Fort Sam Houston, Texas, in 1935. He quoted Major Albert Bowen's roentgenologic description and thus summarized the disease:

> Acute pneumonitis is used as the designation for a form of respiratory infection characterized by a benign course, few physical signs and roentgenologic evidence of a localized inflammatory process in the lung.

4. Dr. Hobart A. Reimann [1] reported eight cases of "atypical pneumonia" from the Jefferson Medical College and Hospital. He said:

> The strikingly similar clinical features of the cases reported suggest that the condition belongs to a disease group not conforming to influenza or the usual form of the common cold but included in an undifferentiated group of infections of the respiratory tract, often called tracheobronchitis, capillary bronchiolitis or bronchopneumonia.

These eight cases were similar in many respects to our few cases of serious involvement in which the pathologic process spread rather widely through both lungs. Obviously at a large city hospital it would be only the patients with rather severe or prolonged disease who would be likely to receive hospitalization, a situation quite different from that in a university or army post. In spite of this disadvantage, Dr. Reimann shrewdly deduced that his eight cases may have represented "the severe uncomplicated form of an otherwise mild and commonly encountered infection."

CONCLUSIONS

1. In a fifteen month period quite free of pandemic influenza, we have observed among the 6,569 students at Cornell University in Ithaca an epidemic of eighty-six cases of acute infection of the respiratory tract in which roentgenograms of the chest revealed typical fan-shaped areas of increased density.

2. On the evidence presented we have concluded that these areas of density were not areas of true consolidation or pneumonia.

3. We suggest that the most descriptive title of this disease is acute interstitial pneumonitis.

4. Though this is apparently a new disease in this area, it is probably identical with the "acute influenza pneumonitis" described by Major Albert Bowen as occurring in Hawaii from 1931 to 1934, with the "acute pneumonitis" described by Dr. William H. White as occurring in Texas in 1935 and with the "atypical pneumonia probably caused by a filtrable virus" described by Dr. Hobart A. Reimann as occurring in Philadelphia in 1938.

5. In areas where acute interstitial pneumonitis is found, all patients with an acute infection of the respiratory tract with a temperature rising above 101 or 102 F. should have a roentgenogram of the chest made for the purpose of excluding pneumonitis or making possible a more accurate prognosis if that disease is present.

THE DETECTION OF TUBERCULOUS INFECTION

COMPARATIVE VALUE OF THE PATHOLOGIC EXAMINATION, THE TUBERCULIN TEST AND THE X-RAY EXAMINATION

J. ARTHUR MYERS, M.D.
MINNEAPOLIS

In the offices of large numbers of physicians in the United States, the examination for the presence of tuberculous infection has become as routine as that for syphilitic infection. Literally millions of such examinations are performed annually. The procedure now in practice has been extremely effective in leading to the detection of unsuspected pulmonary tuberculosis.

The Surgeon General of the United States Public Health Service, Dr. Thomas Parran, has seen the great value of this program and has said that the entire population of the United States should be tuberculin tested and that x-ray examination should be made of the chests of the reactors together with the other phases of the examination necessary to diagnose the existing tuberculosis in this country. Yet Lumsden, Medical Director, United States Public Health Service, has cast disfavor on the scheme following a small personal survey. This dissenting voice may have created doubt in the minds of a few who have not had experience with the test or are only beginning to use it.

As it is only the person who is infected with tubercle bacilli who becomes ill from tuberculosis, the first point to be determined in any medical examination is whether such infection exists. Three methods have been used to determine the presence of tuberculous infection, namely the pathologic examination, the tuberculin test and the x-ray examination.

THE PATHOLOGIC EXAMINATION

In 1876 Parrot observed that when tuberculous involvement is detected in the tracheobronchial lymph nodes there is nearly always a primary focus in the corresponding lung. In 145 cases examined he did not fail to find the lung focus. His student Hervouet emphasized the fact that the postmortem examination must be done with great care and that the making of a few sections of the lung would not suffice because some of the primary foci are extremely small, scarcely exceeding the size of a pin's head. Hutinel reported exceptions, that is, tuberculous foci in the tracheobronchial lymph nodes when no focus could be found in the lung, but he believed that this finding was due to the minute size of the pulmonary focus.

In 1898 Kuss said that primary tuberculosis in childhood cannot be diagnosed clinically but can be found at postmortem by painstaking examination. He pointed out that this condition is characterized by a small tubercle usually located just beneath the pleura, which nearly always results in involvement of the lymph nodes at the lung root. He found that the size of the focus in the lung varies from that of a hazel-nut to that of the head of a pin.

Read in part before the sixth National Medical Congress of Argentina at Cordoba, Oct. 17, 1938.
Prepared with the aid of a grant from the Research Fund of the University of Minnesota.
From the Departments of Preventive Medicine and Internal Medicine, University of Minnesota Medical School, and the Lymanhurst Health Center.

In 1900 Naegeli found gross or microscopic evidence that tuberculous infection was present in 98 per cent of adult bodies which were subjected to postmortem examination.

In 1916 Ghon dissected in detail the organs of the chest as well as all the other organs and lymph nodes of 184 bodies. "Only in this way," he states, "was I able to detect slight tuberculous lesions in some cases where there had been positive tuberculin reaction." Because of their small size the detection of some of the pulmonary foci was "a very difficult task and often required considerable time." Again he says "The smallest foci were scarcely found at all in the cases with anatomical healing. This fact is of importance: it explains to us why it is often difficult to find such foci. . . ." In five of his cases the foci were located in organs outside the chest.

In 1933 Robertson published a report of his extensive pathologic examinations, which dealt largely with the lesions of the primary tuberculosis complex. He says: "To assert positively that any lesion during life or after death is or is not of tuberculous origin often reveals in the final analysis definite and occasionally humiliating errors. This is no expert, no matter what experience or special training he may have had, who has not been 'fooled' by this disease. . . . It is diagnosed as present when it is not. . . . The patient is assured that tuberculosis is not present when it is. Even macroscopic examination of excised tissues may fail to reveal its hidden presence. Orth demonstrated this fact six years before Koch announced the discovery of the bacillus of tuberculosis, when he found, by the microscope, lesions in grossly normal lymph nodes of animals fed on fodder infected with tuberculous material. The patient or his physician is told that the tuberculosis which he once had has been completely healed. Such a statement can never be made with any great degree of certainty and it is my purpose here to emphasize this fact."

Calcified lymph nodes and primary pulmonary foci have been ground and inoculated into guinea pigs by many workers to determine the presence or absence of virulent tubercle bacilli. Lubarsch, Rabinowitsch and Wegelin have recovered tubercle bacilli from as high as 50 per cent of such lesions. Opie and Aronson obtained positive results in 30 per cent of 169 bodies in which the lesions were thought to be apparently healed. Feldman examined microscopically and by guinea pig inoculation lesions of the primary complex from sixty-eight human beings. Although there was evidence of histologic activity in a considerable number, in only one was he able to demonstrate the presence of viable or virulent tubercle bacilli. He questions whether or not the evidence of histologic activity may not have been due to the presence of silica, which was demonstrated in these lesions. He finds that even morphologic studies cannot determine the presence or absence of viable or virulent tubercle bacilli in the lesions of the primary complex. Thus, apparently the infection completely dies out in a considerable number of the lesions of primary complexes and in others the bacilli remain alive and serve as a potential threat to the future health of the individual.

Sweany has established that pure bone develops around the foci in approximately 25 per cent of cases in man and that when the lesions of the primary complex are well calcified or ossified the capsule may be resorbed.

Thus the detailed pathologic examination is a highly accurate method of detecting the presence of the primary tuberculosis complex (tuberculous infection). Unfortunately the majority of them are located so remote from the surface that they are not available for antemortem examination.

THE TUBERCULIN TEST

Tuberculin prepared by different laboratories or even separate lots by the same laboratory may vary considerably in potency. Therefore extensive studies have been conducted by such workers as Dorset, Long and Seibert, who have determined that it is the protein fraction of the tubercle bacillus which sensitizes the tissues of the infected individual. Moreover, they have produced purified protein derivative. While this has not rendered old tuberculin obsolete—extremely valuable when prepared in such laboratories as that at Saranac Lake—it is a definite step forward. The intensive studies now in progress by Long and Seibert promise a standardized testing substance with a dosage which will be as effective in determining sensitivity of the tissues to tuberculoprotein as is possible to attain.

Lumsden says "Skin testing with any of the tuberculin preparations now on the market or otherwise amply available as a sole means of establishing an epidemiological index or rate of incidence of tuberculous infection in the general population of a community or region is of questionable value or definitely futile." I see no justification for this statement; a discrepancy (not as great as that reported by Lumsden) has been recognized for a long time. As early as 1893, Bang of Denmark called attention to the fact that in cattle the occasional animal which did not react to the tuberculin test had unmistakable tuberculous lesions demonstrated at postmortem examination. He said: "But the imperfections of tuberculin mentioned here are eclipsed by its good qualities. According to my experience, which is founded on a very great number of autopsies, it is in 10 per cent of the cases at most that tuberculin will be at fault and it is only in a very small percentage of these cases that the fault will be of consequence." In 1898 Reynolds said: "I do not mean to convey the impression that I consider tuberculin absolutely infallible, but I do consider it more nearly infallible than the human eye or sense of touch."

Every one knows that the Wassermann and other equally good tests are not infallible for the detection of syphilitic infection, yet no informed physician would condemn them and even call them futile because of the occasional failure.

There are certain factors absolutely necessary for the successful administration of the tuberculin test:

1. A high grade tuberculin with recently tested potency must be used.

2. For the individual who has not reacted to 0.01 or 0.1 mg. as the first dose, a second dose of 1 mg. should be administered in from forty-eight to seventy-two hours. When purified protein derivative is used, one should always employ the usual second dose for those who do not react to the first. The administration of a sufficient dosage of tuberculin is important, as a 10 to 20 per cent error may result from using only the small dose. For persons beyond middle life, larger final doses may be necessary.

3. If tuberculin is not lodged in the layers of the skin, no reaction will appear even though the tissues are sensitized to tuberculoprotein.

4. Interpretation is best made by palpation. In the absence of induration or edema no reaction should be recorded. Many one or two plus reactions have been based on areas of pinkness or redness and are not an indication of sensitivity to tuberculoprotein.

When adequate care is used in carrying out these four points the number of persons one misses who have foci of living tubercle bacilli in their bodies will be insignificant. If such care is not taken, of course, the results will not tally with previous records.

The evidence of the specificity of a good preparation of tuberculin properly administered now makes a voluminous literature:

1. One can administer the tuberculin test to large numbers of guinea pigs and find no reactors, then inoculate them with living tubercle bacilli; a few weeks later all will be reactors if the test is again administered.

2. Independently the veterinarians have conducted their investigation on tuberculin. The critics and advocates of tuberculin now active in the medical profession had their parallels in this profession forty years ago. The veterinarians have long since settled their controversy because the immediate postmortem examination of the carcass was proof positive of the specificity of the test. In the United States, tuberculosis among the 58,000,000 cattle, as manifested by the tuberculin reaction, has been reduced since 1917 to one half of 1 per cent or less in all but nine of the 3,134 counties. In 1917 there were 40,746 cattle condemned for tuberculosis under federal inspection in the United States; in 1938 there were only 2,385 cattle condemned. Was this futile? The veterinarian used the tuberculin test as the "sole criterion" of tuberculous infection.

3. A strain of tubercle bacillus with markedly attenuated virulence, known as BCG, when properly administered to man and animals is capable of sensitizing the tissues to tuberculoprotein.

4. We have observed 643 students of nursing and medicine who were nonreactors to tuberculin but who soon after exposure to patients suffering from contagious tuberculosis presented strong reactions. Boynton found that the rate of tuberculous infection among students of nursing in a general hospital service was 100 times greater than among students in the college of education, while among students in a special tuberculosis service it was 500 times greater than in the college of education. Among eighty-five students of nursing and medicine who developed lesions which could be located during life by one or more phases of the examination, not one failed to react to tuberculin.

5. When a contagious case of tuberculosis exists in a family, one finds that nearly all other members react to tuberculin. The presence of the tuberculin reaction among children in such families is so universal that the administration of the test to the children is often used in differential diagnosis. For example, a woman reported to one of our chest clinics with evidence of extensive disease in one lung. The x-ray laboratory reported advanced pulmonary tuberculosis. Tubercle bacilli could not be found in the sputum and she did not react to tuberculin. Finally her four small children were brought to the clinic but not one reacted to tuberculin. The final diagnosis was pulmonary abscess with no evidence of tuberculosis.

6. The tuberculin reaction among children often leads to the source of the infection. For example, Edwards of Cleveland administered the tuberculin test to first grade school children and examined the adult contacts of the reactors. In 1937, 163 and, in 1938, 224 previously unreported cases of pulmonary tuberculosis were brought to light in this manner. Can any one speak of a test which results in such accomplishments as "futile"?

7. Ch'iu found that of 446 children who reacted to tuberculin at the average age of 7 years, 15 per cent had fallen ill or had died of tuberculosis ten or more years later, whereas of 772 children who were nonreactors to tuberculin at the average age of 6.6 years only 1.7 per cent had fallen ill from tuberculosis when traced ten or more years later. Can any one say that a test is "futile" which selects the potential future cases of clinical tuberculosis in this manner?

THE X-RAY EXAMINATION

When the x-rays are used as the final diagnosis of tuberculosis, certain physical limitations of this method must be held in mind else the medical scientist will join the ranks of the awe struck public to whom x-rays are still largely magic. X-rays at their best are entirely dependent on the eyesight of the viewer. Some of the physical limitations are as follows:

1. The x-ray examination usually is limited to the chest. Ghon and other pathologists have called attention to cases in which the most minute examination at postmortem revealed no evidence of tuberculosis in the lung or hilus and yet definite foci were found in other parts of the body. Sweany has shown that about 12 per cent of the tuberculous infections are extrapulmonary. This fact immediately gives the x-rays a 12 per cent handicap.

2. On the usual single film exposed in the posterior-anterior diameter, a considerable part of the lung is obscured from view by shadows of the heart, diaphragm, and so on. Sweany has found that approximately 31 per cent of the lesions which can be detected by postmortem examination had their shadows so obscured from view on the antemortem x-ray films. Thus, an additional 31 per cent handicap must be given the x-rays in detecting tuberculous infection.

3. The x-ray examination is such a gross method that areas of disease must be macroscopic in size before they cast shadows on the x-ray film that are visible to the naked eye.

Miller's x-ray and postmortem studies of 400 cases led to the following conclusions: "With a technic of examination based upon careful study, calcification of tuberculous first infection in the thorax is demonstrable roentgenographically in only about one fourth of the existing cases. The superimposition of structures of varying density, the factors of cardiac and intrapulmonary vascular movement and the minute size of many of the calcium deposits are responsible for this. Blood vessels roentgenographed axially produce shadows which may be confused with those of calcium." Since 75 per cent of the lesions which contain calcium are not demonstrated by x-ray examination, this method cannot be set up as the standard method of detecting tuberculous infection.

Even in the small percentage of primary lesions which are located by x-ray examination it usually takes from one to several years before sufficient calcium is deposited so that it can be detected by x-ray examination. Pinner states that he has observed noncalcified primary tuberculosis complexes that were several years old and one such case in which bacteriologic evidence

of tuberculosis extended over seven years preceding death. Thus, if one were to use the x-rays to determine the presence of infection to find its source, the persons responsible for the infection would continue to disseminate bacilli or even die before their disease would be detected. On the other hand, the tuberculin reaction is definitely present from three to seven weeks after infection occurs and one can immediately seek the open case responsible for the infection. Sweany has shown that 12 per cent of the lesions found at postmortem cannot be detected by x-ray examination because they are too small or too new to cast shadows. Thus another 12 per cent handicap accrues to the x-ray examination.

4. The careful pathologic studies of Sweany have shown that many lesions of the primary tuberculosis complex become almost completely resorbed after fifteen to twenty years, thus casting no shadow on the x-ray film. There is another very definite group of primary lesions which do not form calcium deposits. This, together with those which resorb, constitutes another 25 per cent handicap for the x-rays.

Thus, according to the postmortem work of Sweany, the x-ray examination has a total handicap of 80 per cent in the detection of the lesions of primary tuberculous infection.

If the tuberculin reaction developed in only 20 to 25 per cent of animals inoculated; if it had led to the discovery of only 20 to 25 per cent of the tuberculous cattle of this nation; if it had aided us in finding only 20 to 25 per cent of infected children, certainly we would not be using it as our best standard in the detection of tuberculous infection; yet a 20 to 25 per cent effective standard has been relied on in the report of Lumsden.

5. Even the shadows we do see on the x-ray film are not diagnostic of etiology; those cast by tuberculous lesions may be identical with those of lesions of entirely different etiology. Gloyne of London says: "Thus in the case of hilus shadows an accurate phraseology was certainly needed for what we saw, but when we added the word tuberculosis, we made an inference from the observed facts which we now know to have been often wrong. A similar tendency is creeping in with regard to miliary shadows. We are apt to describe them as miliary tuberculosis. But there is a group of cases in which these shadows disappear after some months and are unaccompanied by the usual symptoms and signs of serious illness. Now miliary tuberculosis is a pathological term with a well defined meaning denoting a fatal disease and I cannot help feeling that our minds will be all the clearer if we can give to the new science of radiology a terminology of its own which cannot be confused with pathology."

Moreover, it is impossible from a shadow on the x-ray film to differentiate between shadows cast by bone, calcium or dense deposits of fibrous tissue. There are causes of calcification in the lungs and hilar region other than tuberculosis.

Frimann-Dahl and Waaler made postmortem examinations of 200 bodies which had previously had x-ray examination. They identified the primary complex in forty-two. They also studied the nontuberculous lesions which had produced shadows so easily misinterpreted for parts of primary complexes. In forty-eight cases there were ossifications and calcifications and thickened pleura not due to tuberculosis. Pieces of wood and cellulose around which calcium had been deposited were found immediately subjacent to the pleura in two cases. Ossifications between the alveoli were found in seven. Emboli and thrombi which had calcified were found in six cases. They also found the cause of the densities on the x-ray film in some cases to be due to silicotic nodules. I have seen pieces of lead in the chest and small remains of iodized oil in the bronchial tree cast shadows which were interpreted as representing lesions of the primary complex until the history revealed the true condition.

6. Krause called attention to the gradual loss of sensitiveness to tuberculin if reinfections do not occur. On a number of occasions attention has been called to the disappearance of allergy as revealed by the tuberculin test among children at Lymanhurst. This has also been observed by those working with BCG; that is, after this substance has been administered, sensitiveness of the tissues reaches its height, following which it may wane and finally disappear as far as can be determined by the tuberculin test. It is believed in such cases that the BCG has completely died out.

When all tubercle bacilli in the lesions of the primary complex have died there remains nothing except the "shells" in which they formerly lived. Tuberculosis is no longer present, regardless of the shadows that may be seen on the x-ray film. Such persons if not reinfected apparently lose their sensitiveness to tuberculin and are therefore nonreactors.

The x-rays are limited by their very nature in two opposite ways. They fail to record or at least we fail to see shadows of all the lesions whether due to minute size or obstructions in the chest and at the same time they record shadows of nontuberculous lesions as well as those of previous tuberculous lesions which no longer harbor virulent bacilli and which have no more clinical significance than an appendicitis scar.

As long as one can submit the same x-ray film to four different roentgenologists without one knowing of the readings of the others and receive three or four entirely different interpretations and as long as one can submit a film to a roentgenologist and receive a definite interpretation on one day and a month later submit the same film to the same roentgenologist and receive an entirely different interpretation, it seems more than likely that many of the differences which have been reported with reference to calcifications are due to errors in interpretation rather than to actual differences in the pathologic condition. Assuming that films have been made by the best possible technic there remains one important essential, namely that shadows be described by a physician who knows the limitations of the x-ray examination.

RECENT REPORTS OF DISCREPANCIES BETWEEN THE TUBERCULIN TEST AND THE X-RAY EXAMINATION

Recently several reports of discrepancy between the tuberculin test and the x-ray film have been made. For example, Nelson and his associates found among 198 children who reacted to tuberculin that eighty-five (42.9 per cent) had what they considered definite roentgenologic evidence of calcification, forty-three (21.7 per cent) had questionable evidence of calcification and seventy (35.4 per cent) had no evidence of calcification. Among sixty-two children who were nonreactors to tuberculin they found what they considered definite roentgenologic evidence of calcification in twenty-seven (43.5 per cent), questionable evidence in five (8.1 per cent) and no evidence in thirty (48.4 per cent). They conclude that low grade or healed tuberculous lesions

in children may exist when the tuberculin reaction is negative or only questionably positive.

Among 1,220 children examined, Crimm and Strayer state that 619 (50.7 per cent) had primary tuberculosis as evidenced by calcification in the lungs, while among 1,998 adults so examined 447 (22.4 per cent) showed evidence of such calcification. The result of the tuberculin test is not given

Crimm and Short reported 191 cases of children and young adults who did not react to tuberculin but who they believe had at some previous time acquired the primary infection of tuberculosis from x-ray evidence of focal areas of calcification. In seventy-five persons who two or three years before were reported as one plus or two plus reactors, they found that 18 per cent had become nonreactors. Over a period of four years they saw four patients who were previously nonreactors who became reactors.

TABLE 1.—*Nonreactors to Tuberculin, January 1922 Through May 1931*

	Number
Incomplete or unsatisfactory examinations	394

Pleural changes	91
Bronchiectasis	34
Questionable or slight calcification	76
Slight calcification	23
Moderate calcification	9
Calcified nodules throughout both lungs	2
Fibroid and calcified deposits in apex only	1
Advanced pulmonary tuberculosis	2
Pulmonary abscess	1
Pneumonia	32
Total	4,148

Gass and his co-workers examined 1,015 white and 276 colored children from 6 to 19 years of age. They submitted the x-ray films of the chests to five different observers, among whom there was unanimous agreement "as to the presence of definite tuberculous lesions in 32.8 per cent of the tuberculin-positive reactors and 24.7 per cent of the tuberculin-negative reactors. Such lesions were noted on at least four of the five observations in 39.4 per cent of the tuberculin-positive children and 46.2 per cent of the tuberculin-negative reactors."

McKneely made an x-ray survey of 6,000 children at Hagerstown, Md., and reported that 963 showed evidence of pulmonary tuberculous infection. Among 2,837 children who were nonreactors to tuberculin approximately 13 per cent had what he considered x-ray evidence, whereas among approximately 700 children who reacted to tuberculin there was x-ray evidence in 20.6 per cent. McKneely says: "In summary, tuberculin testing followed by roentgenographic examination of the reactors in the Hagerstown school children would have missed 85 per cent of the children with tuberculous lesions which were revealed by an x-ray survey. These results seem to show also that the reaction to the tuberculin test is almost unrelated to the roentgenographic diagnosis in this group of school children. Clearly, this finding appears incompatible with much that is believed to be true about tuberculosis and the tuberculin test. The first question which may be raised concerns the accuracy and correctness of our technics, and interpretations. These have been checked as carefully as possible and to date no basic error has been found." One wonders whether man's inability to determine etiology from the x-ray film is not basic enough as far as error is concerned.

Lumsden and his co-workers examined 4,400 scho children from 6 to 19 years of age in Coffee Count Ala., and Giles County, Tenn. He states that in Gil County 43.2 per cent of the white school children an 25.8 per cent of the colored school children and i Coffee County only 0.6 per cent of the white scho children and only 1.1 per cent of the colored scho children showed lesions "regarded by the authoritie generally as unquestionably healed or arrested primar lesions of tuberculosis." Among the white childre examined in Giles County 46.2 per cent of the tube culin reactors and 42.7 per cent of the nonreactors wer reported to have evidence of calcium deposits reveale on their x-ray films.

If one is working in a community where approxi mately 100 per cent of the children have become infecte with tubercle bacilli, one might expect to find abou 20 per cent with evidence of the primary complexes o the x-ray film. In addition one would find simila shadows of lesions with entirely different etiology. I is possible that in some areas of this country the non tuberculous causes of densities, such as fungous disease and silicotic nodules, are more prevalent than in others Therefore in communities where nearly all the children are infected with tubercle bacilli and the other causes of densities on the x-ray film are prevalent a much higher percentage of shadows so often interpreted as representing the primary complex will be found than in communities where the incidence of tuberculous infection among children is low and the other causes of densities on x-ray film are rare.

Among adults there appears to be a definitely lower percentage who have shadows interpreted as calcium deposits than among children. For example, an examination of 846 students by Scheel of Oslo revealed shadows without calcification which he believed were due to deposition of fibrous tissue in 6.9 per cent of the tuberculin reactors and in only 1.6 per cent of the nonreactors. He found evidence of calcified foci in from 12.2 to 16.2 per cent of the tuberculin reactors and in 0.7 per cent of the nonreactors.

Lees examined 464 medical students at the University of Pennsylvania; 338 reacted to tuberculin and thirty-nine (11.2 per cent) showed evidence of calcium deposits on the x-ray film. Of the 126 nonreactors ten (7.9 per cent) gave evidence of calcium deposits

Among 4,372 students who entered the University of Minnesota in the fall of 1936, 1,004 reacted to the tuberculin test. An x-ray film examination was made of 982 of these, of whom only 140 (14.2 per cent) showed possible evidence of primary complexes such as calcium deposits.

Ylvisaker and his co-workers made x-ray films of the chests of 9,301 adult employees in the home office of the Prudential Insurance Company and found that 762 (8.2 per cent) gave evidence of calcium deposits in the chest.

It is possible that the reporting of definitely smaller numbers of adults than children with evidence of calcium deposits may be due in part to resorption of the calcium, bone, and so on, which Sweany has described.

OBSERVATIONS AT LYMANHURST

At the Lymanhurst School in Minneapolis we have examined 16,824 children since 1921, many of whom have been reexamined periodically. First examinations have been made of infants of a few months and of all other ages throughout the period of childhood. We have observed the same infants and children periodically from the time of the first examination as they grew into

adulthood and have seen some of them reach the fourth decade of life. Thus we have seen the complete evolution of tuberculosis in the human body from the time the individual was exposed, following which parts of the primary tuberculosis complex were occasionally detected by x-ray film in the lung or in the hilus or in both. Among such persons we have seen the primary complex make its appearance as well as acute reinfection forms of disease, such as meningitis, pneumonia, miliary tuberculosis, pleurisy with effusion, and peritonitis. We have seen chronic reinfection forms develop, such as those involving the lungs, the kidneys, numerous bones and joints and the digestive tract.

When these observations began, it was generally assumed that all children had been infected with tubercle bacilli and that therefore the x-ray examination should bring to light evidence of calcium deposits, particularly in the hilar region in the majority. For example, in 1925 in one group of 1,412 children we reported that our roentgenologists had found evidence of calcium deposits in 1,024 (72.6 per cent) and that 55 per cent of those with evidence of calcium on the x-ray film did not react to the tuberculin test. At that time the work of several authors emphasized the fact that deposits in the lung or hilus interpreted as calcium are not always due to tuberculosis.

In 1927 we reported the examinations of 4,500 children of whom the roentgenologist had described evidence of calcium deposits in 3,155 (70.1 per cent). In these 3,155 the tuberculin reaction was present in 1,683 (53.3 per cent). The same year we reported the examinations of 1,772 children among whom the roentgenologist had reported the evidence of calcification in 1,077 (60.7 per cent). Of this number said to have calcium deposits demonstrated by x-ray film, 56 per cent reacted to the tuberculin test. The conclusion was that the discrepancies between the tuberculin reaction and

the x-ray examination "may be accounted for either on the ground that the calcification is due to some healed inflammatory condition of a nontuberculous nature, to tuberculous involvement which has completely died out or to error in interpretation of shadows." When a child was reported to have evidence of calcium deposits revealed by the x-ray film in the parenchyma or hilus, slight rotation of the chest under the fluoroscopic screen examination often would obliterate the shadow. Again, on one film of a child's chest the roentgenologist would report evidence of a definite calcium deposit in the hilar region, whereas, on the next examination of the same child's chest no such evidence would be reproted. Structures such as blood vessels seen on end were responsible for many of the reports of the presence of calcium in our previous examinations. About this time reports were

Pneumonia	14	

appearing in the literature calling attention to the work of others who had observed this error, notably that of McPhedran.

By 1930 the interpretations of our x-ray films were so much in error that they were really of little value in the continuation of our studies. Therefore they were reinterpreted in the light of new information.

In table 1 are grouped those who did not react to the tuberculin test and those with incomplete examination with reference to tuberculin and x-ray examination who registered in our clinic before June 1, 1931. The total group consists of 4,148 individuals, 394 of whom were not adequately examined. Thus the group with satisfactory examinations consists of 3,754 children; 3,643 (97 per cent) had no evidence of calcium deposits reported on the x-ray film, while 111 (3 per cent) had such evidence reported, although some of it was questionable. One child had definite pulmonary abscess; two had unmistakable advanced pulmonary tuberculosis. In both of them only the epidermal test was administered. It is probable that in one case desensitization had occurred, as the disease was in the terminal stage when the test was administered. In the second case such an explanation does not seem logical and, unfortunately, larger doses of tuberculin were not administered.

Among the remaining children, thirty-two had shadows in the lung parenchyma which completely disappeared on subsequent examinations. This shows the great advantage of having an opportunity to make periodic examinations. I have seen a number of such cases which on a single examination were designated as tuberculous on the basis of the x-ray shadow. No person, whether a reactor or a nonreactor to tuberculin, should ever be given a diagnosis of pulmonary tuberculosis from the shadows revealed by one x-ray examination. In not a single case of this entire group did we find a shadow in the lung which proved to represent the primary focus in the pneumonic stage.

Table 2 includes 4,737 children who reacted to tuberculin, as they registered in our clinic before June 1, 1931. However, in 134 the x-ray examination was not

done or was unsatisfactory. Of the 4,346 who had x-ray film examinations, 869 (20 per cent) were reported to have definite evidence of calcium deposits. Of the remainder there were 233 who had questionable evidence of calcium deposits on the x-ray film. Among this group of tuberculin reactors it will be observed from table 2 that twenty-five had clinical tuberculosis of the bones and joints and sixty-one had clinical pulmonary tuberculosis.

Because so little evidence of disease was found among our nonreactors, we have not made x-ray films of the chests of nonreactors since June 1931 unless they were demanded by the family or one or more symptoms aroused our suspicion. It will be observed (table 3) that only twelve of the 7,939 children who were examined between June 1, 1931, and Dec. 31, 1938, were not tested with tuberculin. Of those tested only 22 per cent reacted, while among those examined before June 1, 1931, 54 per cent reacted. Among the nonreactors (table 3) only 1,169 had x-ray film examinations and of these only eighteen presented definite evidence of calcium deposits. We have given no consideration whatever to those reported as having possible or probable calcium deposits demonstrated on the x-ray film except to list them. Clinical pulmonary tuberculosis was found in two of these nonreactors.

Among the 1,771 reactors (table 3), definite evidence of calcium deposits was reported in 527 (29.75 per cent), primary foci in the pneumonic stage in twenty-five, clinical pulmonary tuberculosis in thirty-four and nontuberculous pneumonia in fourteen.

As in the group examined prior to 1931 clinical pulmonary tuberculosis was found in sixty-one and since 1931 in thirty-four cases, making a total of ninety-five, all of whom were tuberculin reactors, and since nearly all of this group were in the teen age period, it is almost fruitless to make x-ray films of the chests of children even though they react strongly to tuberculin, before they reach the age of adolescence. It is nearly fruitless to make x-ray films of the chests of children who react to tuberculin to find evidence of the lesions of the primary complex. Therefore our studies have led us to look on the x-ray film of the chests of children as almost a total waste as far as tuberculosis is concerned.

However, when the period of adolescence is reached and on through the span of life, every tuberculin reactor should have an x-ray examination of the chest annually as long as no significant shadows appear and much more frequently if shadows appear which may be due to clinical tuberculosis. Those who present such shadows are subjected to complete examination, including laboratory studies of the sputum and the gastric contents for acid-fast bacilli, periodic red cell sedimentation tests, observation for symptoms, examination for abnormal physical signs, and frequent x-ray examinations of the chest to determine whether the shadow persists and if so whether it changes in size. Even bronchoscopic examination may be resorted to in arriving at the final diagnosis. Thus the diagnosis of tuberculosis often is made only with extreme difficulty; there are no short cuts, such as a single x-ray examination of the chest. Indeed, any one who makes diagnoses without utilizing all of these procedures is open to criticism by experienced physicians. Our experience at the Lymanhurst Health Center has been such that the term "x-ray diagnosis" has become obsolete. We have seen so many errors made that we now accept nothing except a complete examination of which the x-ray film is only a part.

THE RELATION BETWEEN VITAMIN A AND DARK ADAPTATION

SELIG HECHT, PH.D.
AND
JOSEPH MANDELBAUM, M.D.
NEW YORK

I. PURPOSE

Night blindness and similar visual disturbances have long been associated with the nutritional state of the body. In recent years this connection has been traced to the vitamin A of the diet [1] and has become understandable in terms of the chemical relation between vitamin A and the light-sensitive pigments of the retina.[2]

After the establishment of vitamin A as a factor in the visual cycle, it seemed logical to use the properties of vision for the detection of early stages in vitamin A deprivation. Such tests were made by Edmund and Clemmesen [3] with visual intensity discrimination as an index and by Jeans and Zentmire [4] with dark adaptation as a criterion. Other investigations [5] followed and, though some of this work has been found to be perhaps more enthusiastic than critical,[6] it showed that the original idea is probably sound and that under properly controlled conditions some visual properties may be used in diagnosing a lack of vitamin A long before it becomes clinically evident.

The measurements to be reported in this paper were made in an effort to study the behavior of dark adaptation under controlled vitamin A conditions and to ascertain under which circumstances the properties of dark adaptation are indicative of preclinical avitaminosis A.

II. DARK ADAPTATION

Dark adaptation is a familiar phenomenon. On coming from the brightly illuminated outdoors into a dimly lighted room, one can see hardly anything at first, but, as one stays indoors, objects slowly take shape, and after fifteen or twenty minutes they appear so clear that one recalls the initial visual obscurity with astonishment. The process of achieving this good vision is called dark adaptation. It was first described by Aubert [7] in 1865 and first measured by Piper [8] in

From the Laboratory of Biophysics, Columbia University.

This research was aided by a grant from the Rockefeller Foundation.

An account of this work was first given March 29, 1938, to the Round Table on Nutrition and Public Health sponsored by the Milbank Memorial Fund and held at the New York Academy of Medicine. It was later reported briefly at the Vitamin Round Table of the Clinical Congress of the Connecticut State Medical Society at New Haven, Conn., Sept. 21, 1938. Part of the results have been published as a preliminary note in Science (88: 219 [Sept. 2] 1938).

1903. Since then it has been extensively studied, and now there exists a body of information which is sufficient to describe it quantitatively.[9]

Measuring dark adaptation involves finding the minimum light which must illuminate a given surface in order to render it visible. This threshold illumination is high when one enters a dark room and decreases as one stays in the dark. The most striking thing about this change in visual threshold is its range; it can easily cover a gamut from 100,000 units of light intensity at the beginning to 1 unit at the end of dark adaptation.

The retina is neither a simple nor a uniform structure. It possesses two kinds of receptors—rods for vague colorless vision at low light intensities and cones for acute color vision at high intensities—and these are distributed in a definite and characteristic pattern over the surface of the retina.[10] Since dark adaptation is accomplished by both rods and cones, their distribution and properties determine the precise nature of the dark adaptation corresponding to any region of the retina. Unless understood, these complexities will trip the innocent investigator who is unaware of the accumulated visual knowledge of the last twenty-five years.

It would obviously be out of place to present this information here, especially since it has already been reviewed in detail elsewhere;[9] therefore we may state categorically that there are at least six specifications which must be made in order that measurements of dark adaptation may be numerically precise and quantitatively valid. These conditions are (1) the intensity and (2) the duration of the light present before dark adaptation begins and (3) the area, (4) the retinal location, (5) the color and (6) the duration of the light used for measuring the course of dark adaptation.

In order to understand what these specifications involve, it is well to look at the measurements of dark adaptation shown in chart 1. For the moment consider only the upper set of points in the chart. They are single measurements which record the light intensity which the observer can just barely see as he stays in the dark. Time is plotted on the horizontal axis on an ordinary linear scale. Light intensity, however, is plotted on the vertical axis on a power or logarithmic scale. On such a scale 1 means 10 units, 2 means 100 units, 3 means 1,000 units, and so on. The most important reason for using a logarithmic scale is the large range of intensities covered by the data. A simple linear plot would have to be enormous to show any detail in such a range and would cramp some portions of the data and exaggerate others. Another virtue of a log plot is that a percentage error always occupies the same distance; a 10 per cent error is the same size whether applied to 1 unit or to 1,000 units.

Chart 1 shows that dark adapation proceeds in two steps. The first is rapid and is over in a few minutes; the second is late in starting and goes on for a half hour or more. It is now well known that the rapid first adaptation records the behavior of the cones of the retina, while the delayed and slower second adaptation reports the function of the rods. When, as for chart 1, the measurements have been made with violet light, this is brought out by the sharp and easily noted color difference between those thresholds which are determined by the cones and those made by the rods. Even a completely inexperienced observer records the fact that at the threshold the lights corresponding to the first section (solid circles in chart 1) appear violet or blue, while those composing the second section (unfilled circles) show no color at the threshold.

The six conditions under which the measurements are made influence profoundly the relative extent, the duration and even the form of the two parts of the dark adaptation curve. Thus the brightness and duration of the light adaptation which precede dark adaptation will fix the time of appearance of the cone-rod transition; after prolonged exposure to high intensities, the break may not come before fifteen or sixteen minutes, whereas after short exposure to low intensities it may come after half a minute or even less. The same is true of the color of the light used for measuring the threshold. Measured with red light, dark adaptation may show mainly the first, cone section, followed perhaps by a very slight rod section, which appears after thirty minutes; while with violet light the cone portion may hardly show, and only the rod, secondary section will be dominant. Similarly the area and location of the part of the retina used in the tests share with the other factors the control of the course of dark adaptation.

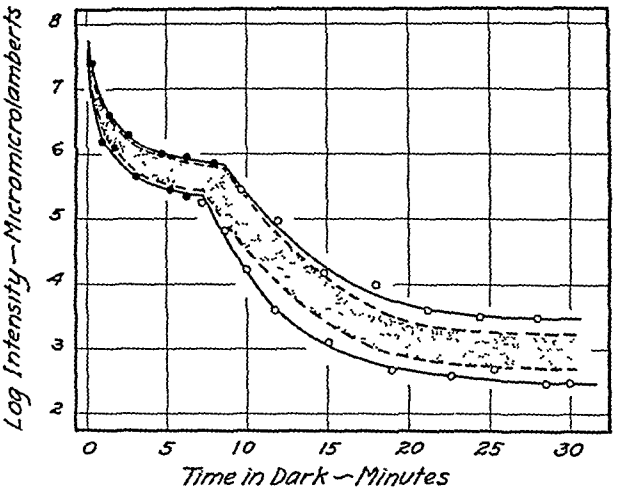

Chart 1.—The course of dark adaptation in 110 normal persons. The points represent the single measurements made with two subjects yielding the highest and lowest values of the final threshold. The dotted area contains 80 per cent of the population. Note the cone primary adaptation marked with filled in circles, the rod secondary adaptation marked with unfilled circles and the cone rod transition time.

III. STANDARD CONDITIONS AND APPARATUS

Since all these circumstances determine the nature and course of dark adaptation, it took many preliminary tests and a long experience with visual measurements for us to formulate the best conditions for routine measurements. The conditions we finally adopted as standard were chosen for their physiologic reasonableness.

To begin with, the precise effects of nutritional and pathologic conditions on the course of dark adaptation are not known. We therefore chose such a light adaptation that both cone dark adaptation and rod dark adaptation are separately and adequately shown in the measurements. This means a light adapting field, occupying about 35 degrees visual angle, whose brightness is about 1,500 millilamberts. The exposure

to it is for three minutes, which is long enough to produce the main effect and short enough to keep the subject from being bored.

The test field occupies 3 degrees visual angle in diameter as a compromise between a smaller field, which reports the behavior of a uniform part of the retina, and a larger field, which is more easily seen by untrained subjects. The test field and the light adapting field are viewed 7 degrees nasally with the right eye. This position was selected because at this point the population of retinal rods and that of cones are more nearly

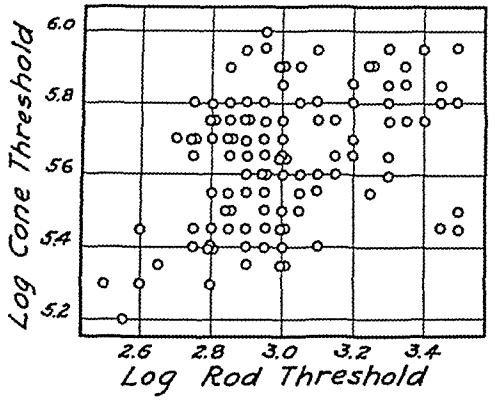

Chart 2.—Relation between final rod threshold and final cone threshold shown by 110 persons. The two thresholds are obviously connected, but the correlation is less than half perfect. As chart 4 shows, age is the biggest factor in disrupting the correlation.

equal than in the center of the retina or farther in the periphery. Moreover, the luminous fixation point used to keep the eye centered and steady is thus sufficiently far from the measuring area so as not to interfere with its function.

The measuring light is from the extreme violet end of the spectrum. This makes the rod section always maximal in range and furnishes the clear color distinction between cone function and rod function already referred to and shown in chart 1. The measuring light is exposed in flashes of one-fifth second, which is long enough to produce a good perception of the test area and short enough to be near the retinal action time.

These specifications may be duplicated by any one who will set up apparatus for controlling intensities, times, positions and areas. However, for convenience Hecht and Shlaer[11] have designed an adaptometer which not only incorporates these specifications but is so arranged that they can be varied in case it is necessary to investigate other aspects of dark adaptation under different but controlled conditions. This apparatus and the mode of its use have been described in detail and therefore need not be reproduced here. Throughout the present research we used an apparatus of this design and followed the recommended procedure.

In barest outline, this procedure consists of two parts. First the eye is exposed to the standard light adaptation. Then as the subject stays in the dark the intensity threshold of the selected region of the retina is measured with flashes of violet light. The exact steps in the measurements are important, and the various parts of the apparatus are concerned merely with carrying them out expeditiously and with precision. Each datum secured represents the just perceptible light intensity at a certain time in the dark, and between ten and fifteen such determinations yield a curve of dark adaptation similar to those shown in chart 1.

Measurements of dark adaptation made in this way reach a final threshold whose brightness is about one thousand-millionth of a lambert. This brightness represents approximately the appearance of a white card illuminated by a candle 1,000 feet away and corresponds roughly to an illumination of one millionth of a foot candle. The logarithms of such fractional numbers are negative and inconvenient to use. We therefore adopted a unit much smaller than the lambert: this is the micromicrolambert ($\mu\mu$l), which is a lambert $\times 10^{-12}$, or one million-millionth of a lambert. All possible values of the threshold are thus given by positive logarithms.

IV. NORMAL VARIATION

Before making any dietary experiments, we wished to ascertain the normal distribution of the characteristics of dark adaptation. For this purpose we made routine measurements with 110 persons, most of whom had university associations, as faculty, students, wives or children. The reason for choosing university people is not merely the obvious one of convenience but rather the practical one of normality. University people are more likely to represent a well fed group, well balanced in its dietary habits. That this judgment is right will be evident later. The measurements are all single readings and first performances. This makes them comparable to measurements which are likely to be made for ordinary diagnostic purposes.

Chart 1 gives the type of result we secured. The two sets of measurements actually shown are of the two persons who yielded the extreme final rod thresholds, the highest and the lowest. The stippled band between the two dashed curves is drawn to include the data of eighty-eight people, or 80 per cent of our population. The chances are therefore quite high that

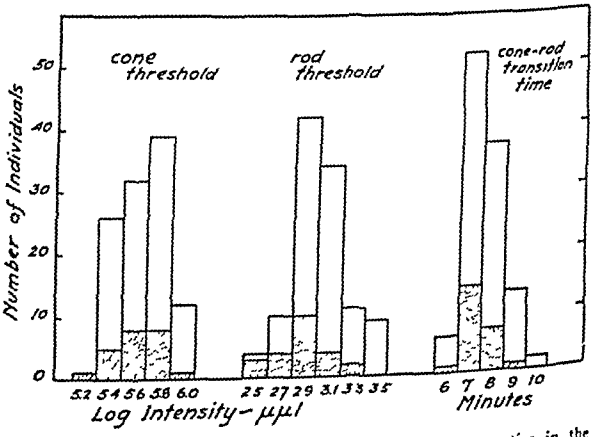

Chart 3.—Distribution of the three dark adaptation properties in the population. The stippled areas represent females. Obviously sex does not affect the distribution.

an average person when tested will show a dark adaptation curve which falls in this band.

It so happens that this stippled area in the cone region actually contains 93 per cent of all the cone measurements. This is because cone threshold and rod threshold are only partially correlated. Chart 2 records the final cone and rod thresholds of our population. It is evident that there is a general tendency

11. Hecht, Selig, and Shlaer, Simon: An Adaptometer for Measuring Human Dark Adaptation, J. Optic Soc. America 28: 269-275 (July) 1938. This instrument was made for us by Mr. O. C. Rudolph, 55 Van Dam Street, New York City.

for the two thresholds to vary in the same direction but that the correlation is not high. Determined in the usual statistical manner the correlation coefficient of the two final thresholds is 0.44, where 1 is a perfect correlation and 0 is no correlation.

After studying the various properties of the course of dark adaptation, such as the speed of adaptation and time for the cone-rod transition, we selected three aspects which seem to possess quantitative value as description. These are the final cone threshold, the final rod threshold and the cone-rod transition time. Chart 3 shows the distribution of these properties in our population. The cone threshold distribution appears slightly skew; the other two distributions are approximately symmetrical. The stippled areas represent females and the clear areas males. Obviously sex does not affect the distribution.

Age has some influence on dark adaptation. This is most clearly evident on the final cone threshold. Chart 4 shows that the cone threshold slowly rises with age, as evidenced by the position of the distribution maximum for the different age groups. Because violet light is used in these measurements, it is possible that the rising cone threshold is due to the yellowing of the ocular media with age. In that case the same rise in the threshold should be shown by the rods. However, the rod threshold shows no such obvious change with age. There is a subtle shift in distribution of rod thresholds with age which deserves to be pointed out, but we lay no emphasis on it. Note in chart 4 that for the 15 to 20 year group the distribution is skew to the left of the maximum, for the 21 to 25 year group it is symmetrical, for the 26 to 39 year group it is definitely skew to the right of the mode and for the 40 to 65 year group it is strongly skewed to the right. On the other hand, the cone-rod transition time is unaffected by age, the distribution maintaining the same maximum and the same degree of asymmetry throughout.

How much of the spread covered by the measurements is day-to-day variation and how much is fixed individual difference? Our experience with visual measurements indicates a maximum day-to-day intensity variation of 0.3 log unit. It may well be that for several days or even weeks of measurement of a visual function a person is consistent to within less than 0.1 log unit. Then, perhaps after a short lapse of time or quite suddenly as the result of fatigue or of a night out or even for no apparent reason, he may change and give values which fall within about 0.3 of the previous readings. Previous measurements with dark adaptation follow this expectation. However, for routine purposes we chose six subjects at random and measured them five or six times in four weeks. The resulting threshold variation for each person corresponds with previous experience, and it would serve no useful purpose to reproduce the measurements. A range of 0.3 log unit is a factor of 2 in actual light intensity. This means that, if the threshold today is 1, next week it may be 2 and it will continue to lie between these values. Considering that the total threshold change during dark adaptation is about 4 log units, or 10,000 to 1, this is a comparatively small variation.

This day-to-day fluctuation is not due to experimental or instrumental errors. In the apparatus we use, it is a simple matter to set a reading to 0.1 log unit, and a careful investigator can set it to considerably less. The variation encountered among the population therefore represents not only the day-to-day fluctuations that any individual might be subjected to but in addition real differences between the individuals.

V. BASIS FOR INDIVIDUAL DIFFERENCES

The total spread of final rod thresholds in charts 1 and 3 is 1.0 log unit, or 1 to 10 in linear intensity units. Deducting 0.3 log unit as the expected day-to-day variation leaves 0.7 log unit as the range within which individuals vary one from another. It is naturally tempting to suppose that the distribution in this range is due to the variation of the vitamin A content of the diet and of the body and that an individual's position in the population spread depends on his normal eating habits. Our experiments do not bear this out.

Of the eleven persons whose final rod thresholds lie in the extreme upper range, we selected six for study. Their diets seemed well balanced and contained plenty of vitamin A, and none of them showed any of the usual clinical signs of A deficiency; moreover, none of

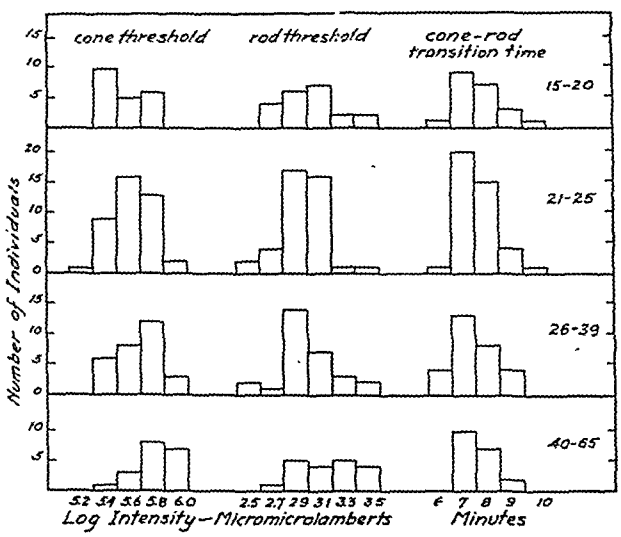

Chart 4.—Distribution of dark adaptation characteristics according to age. The cone threshold is most affected by age, the rod threshold only slightly and the cone-rod transition time not at all.

them had noticed any subjective difficulties in dark adaptation. We fed them 50,000 units of vitamin A daily for three and four weeks in addition to their regular diet. Five of the six showed no changes in their dark adaptation curves during this period, that is no change that did not fall within the normal day-to-day variation evidenced by any person whose curves are measured repeatedly. Obviously neither the daily fluctuations nor the differences between normal persons can be attributed to the daily fluctuations or the consistent differences in the vitamin A content of the diet. This is also confirmed by the case of one of the investigators in our laboratory whose final rod threshold has remained consistently among the highest despite the fact that he has eaten all sorts of supplementary vitamin A and carotene in the last two years.

Our study is thus in contrast to the investigation of 162 medical students in Boston made by Jeghers.[12] He reported that fifty of these students were subnormal in their dark adaptation. Of the fifty, at least twenty-seven were described as clinically aware of their poor dark adaptation and fifteen as possessing cutaneous

12. Jeghers, Harold: The Degree and Prevalence of Vitamin A Deficiency in Adults, J. A. M. A. **109**: 756-761 (Sept. 4) 1937.

symptoms in addition. All those tested improved under treatment, most of them strikingly. Our own group contains sixty students, undergraduates and graduates. Their dark adaptation characteristics dominate the first two age groups in chart 3 and do not differ from those of the other groups except as age influences their distribution. Actually our six persons with high thresholds are all students, and five of them showed no change with supplementary feeding of vitamin A. The sixth will be discussed in a moment.

The differences between our subjects and those of Jeghers may be quite real; however, these differences may be exaggerated by the apparatus used by Jeghers, namely the biophotometer. Other studies with this instrument have previously failed of complete corroboration, and the instrument itself may be criticized on several grounds. In particular, Jeghers [12] reported a sharp correlation between biophotometer readings and the estimated vitamin A content of the diet of his medical students. Such a correlation has failed to appear in a similar study by Isaacs, Jung and Ivy,[6] who have shown that the statistical errors involved in

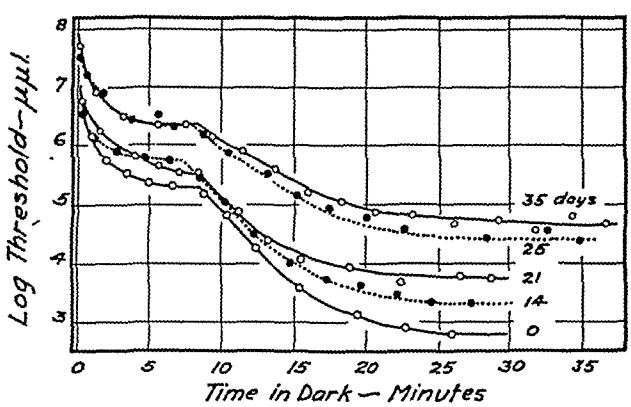

Chart 5.—Dark adaptation measurements made with one person at various times in the course of a diet practically free from vitamin A. The filled and unfilled circles merely keep the different sets of measurements apart and are smoothed by dotted and continuous lines respectively. Compare this chart with chart 1 and note how soon the data reach a level above the normal.

the use of the biophotometer are too large for such a study to be significant. The biophotometer does not incorporate in its structure and recommended procedure many of the critical specifications for measuring dark adaptation already referred to and fails to link its results with physiologic knowledge. One of the major errors is the lack of a fixation point; this failure to define the retinal area measured probably results in considerable erratic variation among individuals depending on the skill and aptitude of the subject.

In our study, even though in general the position of a normal person in the threshold spread is probably determined by other things than his diet, it is conceivable that one whose threshold is normally low may, on account of a deficient diet or of another bodily condition, be shifted to a higher position in the threshold range. Of the six subjects with high thresholds selected, one turned out to be such a person.

To begin with, his final rod threshold corresponded to log I = 3.5 and his cone-rod transition time to ten minutes, both of which are maximal in our population. Like the other five persons, he had an apparently normal diet. Yet, unlike that of the others, his dark adaptation was distinctly altered by the supplementary feeding. At the end of a week his final rod threshold had fallen from log I = 3.5 to 3.0 and at the end of three weeks it reached nearly 2.5. Moreover, during this time his cone-rod transition time had shortened steadily from ten minutes to six.

It will be apparent in a moment that ordinary dietary avitaminosis A does not change the cone-rod transition time, even though it may alter the cone and rod thresholds considerably. On the other hand, avitaminosis due to cirrhosis of the liver alters not only the thresholds but also the cone-rod transition time, as Haig, Hecht and Patek [13] showed. Apparently catarrhal jaundice also changes the cone-rod transition time.[14] We are therefore inclined to think that the extreme position of this individual in the population, as well as his exceptional response to supplementary feeding of vitamin A, is due to some aberrant factor in his vitamin A metabolism which may later become apparent clinically.

VI. DIETARY AVITAMINOSIS

After having established the spread in the dark adaptation of a normal population, we studied the dark adaptation of four young men on a regimen of decreased vitamin A. First we measured their dark adaptation almost daily for two weeks while they continued their normal and apparently adequate diet. Then we restricted their diet to foods that were calculated to yield at most 150 units of vitamin A daily. In this we followed the data compiled by Daniel and Munsell.[15] No special supplements were given of the other vitamins, because we wished to imitate the conditions under which dietary avitaminosis A would most commonly become established. The diet was maintained for about forty days, after which all four men returned to their normal food habits. Two were given daily supplements of 50,000 units of vitamin A for about six weeks afterward.

In studying the data during this experiment we followed the various properties shown by the dark adaptation curves. In particular we wanted to discover how the three selected characteristics shown in chart 3 behaved during the tests, because in the experiment with dietary avitaminosis A made by Jeghers [12] on himself the measurements were performed with inadequate apparatus and procedure and failed to show what actually happened to the course of dark adaptation. In the recent and similar experiment reported by Wald, Jeghers and Arminio,[16] made since our preliminary notices, the procedure and apparatus have been changed to render the results more revealing of the properties of dark adaptation.

Chart 5 shows five curves of dark adaptation made with one of our subjects during different stages of the deficient diet. Of the three critical properties it is apparent that both the cone thresholds and the rod thresholds are affected by vitamin A deprivation. Rod vision is affected more than cone vision, as evidenced by the more rapid and extensive rise of the rod section during the diet. This confirms the work of Haig, Hecht and Patek,[13] who found more extensive changes in rod function than in cone function in the dark adaptation of patients with cirrhosis of the liver. It is confirmed by the measurements of Wald, Jeghers and Arminio.[16]

13. Haig, Charles; Hecht, Selig, and Patek, A. J.: Vitamin A and Rod Cone Dark Adaptation in Cirrhosis of the Liver, Science **87**: 534-536 (June 10) 1938.

16. Wald, George; Jeghers, Harold, and Arminio, Joseph: An Experiment in Human Dietary Night Blindness, Am. J. Physiol. **123**: 732-746 (Sept.) 1938.

Differing from the clear effect of the diet on the cone and rod thresholds is the complete lack of effect on the cone-rod transition time; this remained the same during all the vicissitudes of the diet for all four subjects.

The parallel behavior of rod and cone functions is shown in chart 6, which records the results with the two subjects who were given supplements of vitamin A after their return to a normal diet. The data of J. M. are about average for the four subjects, while L. W. represents the extreme effects. Each point in chart 6 is the final threshold either of the cone section or of the rod section of such curves as those in chart 5. The thresholds of the last two runs on the normal diet are shown above the diagonally shaded area on the time axis of chart 6; the clear area records the duration of the deficient diet and the black area the subsequent normal diet, supplemented as already described. It is not necessary to stress the similarities of the changes in cone and rod vision. The results confirm those of Haig, Hecht and Patek for the cone and rod thresholds during vitamin A therapy of alcoholic subjects with cirrhosis and are in turn corroborated by Wald, Jeghers and Arminio's study of one instance of dietary avitaminosis.

The important thing which chart 6 brings to light is that, as measured by dark adaptation, the presence of a dietary avitaminosis becomes evident after the very first day of the absence of vitamin A in the diet. Because of the normal day-to-day variation no reliance can be put on such a single early measurement, but the rise in threshold continues steadily and in less than a week of vitamin A lack the rod and cone thresholds in chart 6 have mounted well beyond their daily fluctuations, and a conclusion of decreased visual function can be reached with reasonable certainty. Note particularly that after about ten days of the diet the rod threshold has risen beyond the commonly encountered range included in the band in chart 1 and that a few days later it has reached a value which is higher than the extreme found in only 3 per cent of our normal population. This clearly indicates the normal character of our own population, since so short a period of deficiency sends the measurements beyond the common range.

During this period of a deficiency diet our subjects were instructed to report any subjective or other symptoms noted; with one exception none were reported, though at least one subject did a fair amount of night driving. The one report was made by L. W. toward the end of the period, when he recorded that he had collided with a wall in his home and was surprised that he had not seen it. Evidently most night illumination is well above the threshold of vision.

The return to a normal diet with or without daily supplements of vitamin A did not result in the spectacular recovery of the visual function reported by Edmund and Clemmesen [3] and by Jeghers.[12] As chart 6 shows there is a slightly rapid drop in threshold at first, but this is followed by a gradual decrease in threshold, and it took about two months for our subjects to return to the normal range.

Several times after the administration of a dose of vitamin A we followed the dark adaptation of an experimental subject at intervals during the day, but we observed no striking change. Chart 6 shows one such instance, which is perhaps the only effect that we could call a positive one. It concerns the three points in the rod data of L. W. above the narrow black area. This records a single administration of 100,000 units of vitamin A, and the points above it show the cone and rod thresholds determined in the usual way before the dose and three and six hours after it. The drop in rod threshold is about 0.4 log unit, which, considering the variation shown by L. W. during the remainder of the experiment, is nothing to be certain about and is in a different category from the almost immediate drop to normal reported since by Wald, Jeghers and Arminio.[16] A possible reason for this divergence in results may be that their subject was given supplementary vitamin B during the deficient diet, while ours took only the amounts present in the restricted diet. But this is not the case with the dramatic recoveries reported by Edmund and Clemmesen.[3] Further work will be necessary to clear up this discrepancy.

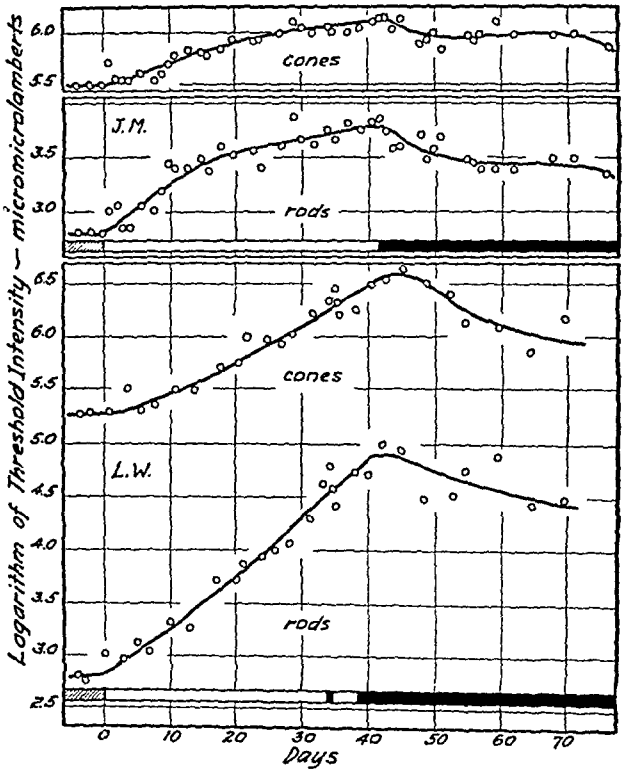

Chart 6.—The final cone and rod thresholds of two subjects on a diet nearly free from vitamin A. The diagonally shaded part represents the normal diet, the clear part the diet free from vitamin A and the black part the normal diet plus 50,000 units of vitamin A daily.

VII. DARK ADAPTATION AND DIAGNOSIS

As a result of these observations we feel certain that measurements of dark adaptation when carried out under properly standardized conditions can be used as an aid in the determination of the vitamin A condition of the body. Normal dark adaptation means a normal vitamin A content of the body, and an abnormal dark adaptation means a disturbance in the vitamin A content.

What normal is remains to be defined precisely, but this definition must be made by others. At present we may take it to mean the dark adaptation and vitamin A content of ordinarily well nourished, healthy persons such as we chose for our survey. It may well be that the common, normal dark adaptation can be improved by supplementary feeding of vitamin A. Our own attempts in this direction have not been successful, but they lasted only from three to four weeks, and more prolonged supplementation may be necessary. How-

ever, even if the commonly found dark adaptation could be improved in this way, it remains to be shown that improvement is desirable. For the present therefore normal had better be accepted in its ordinary usage.

When the dark adaptation of a person is found to be abnormal, it may mean either that his retina is not adequately supplied with vitamin A or that his visual apparatus is defective. Such defects may be congenital, like the absence of cone or rod function, or they may be acquired pathologic disturbances. When these genetic and pathologic possibilities have been excluded, one must next determine the basis for the lack of retinal supply of vitamin A. It may be the diet, in which case the remedy is simple. It may, however, be some other link in the metabolic chain from diet to retina, such as the liver, in which case other signs must be looked for.

It is these possibilities which make us doubtful of the recommendation by Wald, Jeghers and Arminio [16] that the final rod threshold alone may be adequate as a diagnostic sign. Since the final cone threshold also changes during avitaminosis—dietary and pathologic—the recognition of a change in its value serves as a corroboration of the rod data. Moreover, it is not the final threshold

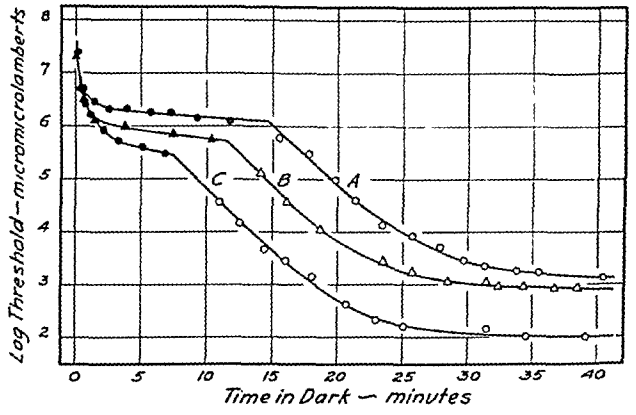

Chart 7.—The dark adaptation of a patient with cirrhosis of the liver, taken from the preliminary report of Haig, Hecht and Patek.[13] The conditions of measurement were slightly different from those here used but near enough for adequate comparison. Curve A was obtained when the subject was on an ordinarily adequate diet, while curves B and C were obtained after 105 and 127 days of intensive vitamin A therapy. Note especially the decrease in cone-rod transition time, as compared with its stationary position in the experiment with dietary avitaminosis recorded in chart 5.

alone which changes but the whole position of the dark adaptation curve on the intensity axis, and it is with much more confidence that one can conclude from the curve as a whole rather than from the position of its final point.

More significant than either of these reasons is the fact that other properties of dark adaptation are also subject to change, and it may be that further study will show characteristic disturbances of adaptation resulting from various diseases. Thus simple dietary avitaminosis does not change the time of the cone-rod transition point, whereas severe cirrhosis of the liver delays its appearance to almost twice the time, even though the final thresholds may be affected to the same extent in the two instances. We think this so important that we reproduce in chart 7 the curves from Haig, Hecht and Patek's study of dark adaptation in an instance of cirrhosis of the liver. Curve A was obtained when the subject had been on a normally adequate diet for three weeks, while curves B and C were obtained after 105 and 127 days of intensive vitamin A therapy. Compare this chart with chart 5 and note especially the way the time for the cone-rod transition gradually shifts to normal. It may well be that this difference in behavior of the cone-rod break is purely a matter of short period avitaminosis versus prolonged deprivation. This in itself would be of significance in diagnosis. For such reasons we feel that it is better to determine the dark adaptation curve as a whole rather than just the position of the final rod threshold.

These reasons apply equally well to the calls that are sure to be made for an apparatus for rapid diagnosis. This is a desirable trend, especially for extensive survey purposes, but we hope that it will not be acted on soon. A rapid procedure can consist only of a shorter light adaptation followed by the determination of the time to reach one or two fixed intensities during dark adaptation. To be reached rapidly these fixed points must be on the cone curve, so that one will lose the value of the cone-rod transition time and of the final rod threshold as aids in diagnosis. It might seem that if one started with a low enough intensity of light adaptation the resulting adaptation would be purely a rod function even if rapidly made. However, for the low light adaptation to be effective it must be preceded by a preliminary period of dark adaptation, which defeats the aim of a quick test. In short, a rapid test can measure only cone adaptation, and too little is known at present of the effects of disease and diet on dark adaptation for any one to select with confidence a point on the curve for use as a fixed criterion. We therefore urge, for a while at least, that authors performing clinical and physiologic investigations with dark adaptation and vitamin A record the whole curve of dark adaptation in their procedure.

SUMMARY

The dark adaptation of a university population of 110 persons, when measured under standardized conditions, shows three properties which are useful quantitatively: the final cone threshold, the final rod threshold and the time for the transition from cone function to rod function. The distribution of these properties is not affected by sex. Age definitely increases the cone threshold but affects the rod threshold only slightly and the cone-rod transition time not at all.

The range over which these properties vary in the population is composed partly of day-to-day variation and partly of individual difference, the latter causing much the wider spread. Individual differences were not the result of differences in the vitamin A content of the diet, and with a solitary exception no significant changes were produced by supplementary vitamin A feeding of persons with the highest thresholds.

Four young men when deprived of dietary vitamin A responded by a steady rise of both cone and rod thresholds which was apparent almost from the first day after the removal of vitamin A from the diet. After about two weeks' deprivation they showed thresholds above any values normally found in the population; their thresholds continued to rise so long as the dietary deprivation was maintained. The return to a normal diet with or without supplementary vitamin A resulted in an initial small rapid drop in threshold followed by a gradual decrease; nearly two months was required for the subjects to return to normal.

Measurements of dark adaptation when made under critically standardized conditions can be used as an aid in the diagnosis of avitaminosis A produced not only by a lack in the diet but by a functional disarrangement in the flow of vitamin A from diet to retina.

THE ENDOCRINE IMPLICATION OF JUVENILE CHONDRO-EPIPHYSITIS

ROBERT L. SCHAEFER, M.D.
FRED L. STRICKROOT, M.D
AND
FRANK H. PURCELL, M.D.
DETROIT

Juvenile chondro-epiphysitis is described as an alteration in shape of the developing epiphyses associated with an apparent aseptic necrosis. Pathologically there may be rarefaction or even cystlike formation and degeneration. Clinically there is possibility of eventual deformity. Roentgenographically it is characterized by the following changes in the developing osseous centers: diminution in size, decrease in density, rarefaction, fragmentation, irregularity of the ossification contour and in general a fuzzy, ragged appearance of the chondro-epiphysial structures. Depending on the various structures showing such x-ray changes, almost innumerable proper or descriptive names have been employed. This conglomeration of proper names is confusing in conditions which, we think, are identical and have the same etiology.

The suggested etiology up to the present time has been entirely theoretical without any modicum of fact. The current popular impression leads one to believe that it is the result of some inflammatory reaction or blood vessel anomaly resulting in poor vascular nourishment. It also has been thought that it is a uni-epiphysial disturbance and that clinically it is associated with pain and swelling.

The significance of this publication is an attempt to prove that juvenile chondro-epiphysitis is due to an endocrine imbalance, specifically to a primary or secondary hypothyroidism in which the tissue differentiating factor is absent, that it is a generalized process involving one or more of the developing chondro-epiphysial structures and that it is at least incipiently asymptomatic.

Engelbach some twenty years ago pointed out the value of the roentgenographic study for osseous development in clinical endocrinology. It ranks today as one of our most useful diagnostic procedures. In the younger age group, from birth to 8 years, it pertains specifically to thyroid function and is related to the time of appearance of the various centers. A *delay in* appearance of the centers is pathognomonic of a hypothyroid state due to the absence of this same tissue differeniating factor. Certainly in this age group the x-ray by far outranks the basal metabolic rate for accuracy because of the evident difficulty in evaluating the latter test in younger children with the ordinary clinical apparatus available.

In the older age group, from juvenility to completion of adolescence, the epiphyses are all present and in a fair state of development. In this period delayed or advanced union gives visual x-ray evidence of gonadal function, early union being indicative of premature adolescence or sex maturity, delayed union being indicative of a gonadal hypofunction.

In 1931 we began to do routine x-ray studies on all children with suspected endocrinopathies, following the plan originally devised by Engelbach and his colleagues Tierney, MacMahon and Shelton.[1] Hence not one joint but from two to four were roentgenographed, depending on the age of the patient. Very early in our studies of endocrine dwarfism we were struck by the frequency of single or multiple involvement of the chondro-epiphysial structures and so originally reported our observations.[2] It soon became apparent that this condition was not peculiar to dwarfism but was being seen with as great or greater frequency in other endocrine conditions displaying signs of hypothyroidism.

The basis for this report is the study of (1) a group of 258 clinically proved endocrinopathic patients in the age range of 8 to 15 years and (2) a control group of ninety-nine assumed normal children in the same age group. Out of the 258 endocrinopathic patients studied ninety-one, or 35.2 per cent, showed a chondro-epiphysial disturbance. Two hundred and eighteen of this group displayed clinical evidence of primary or secondary hypothyroidism, such as roentgenographic evidence of delay in osseous development, decreased basal metabolic rates, increased blood cholesterol or developmental delay. The number of hypothyroid cases showing chondro-epiphysial disturbance was eighty-five, or 39 0 per cent; in other words, all but six cases of *chondro-epiphysitis* were associated with hypothyroidism. Eight hundred and ninety-four joints were roentgenographed, an average of 3.46 roentgenograms per patient. It is believed that the incidence would have been materially increased if more or if all joints had been roentgenographed as a routine. Thirty-eight, or 41.7 per cent. of the ninety-one showing involvement showed multiple epiphysial disturbance. An unusual observation in table 1 is the most frequent involvement of the trochlea of the humerus. More than casual survey of the literature failed to reveal chondro-epiphysitis

in this developing osseous structure. There were only three patients in the entire group who had any symptoms referable to the osseous involvement; two were referred by the orthopedic collaborator and one by a pediatrician,[3] who recognized the possibility of an associated endocrine factor as the cause of the chondro-epiphysitis. It is well to emphasize here that all the

rates, urinalysis, blood count and blood chemistry studies including sugar, nonprotein nitrogen, cholesterol, calcium and phosphorus.

Our control group study was made possible at the Anatomical Laboratory and Associated Foundations of Western Reserve University[4] through the courtesy of the late Dr. T. Wingate Todd.

The records of ninety-nine children who fulfilled our requirements as being free from endocrine imbalance were placed at our disposal for study. The age range was the same as of the endocrinopaths studied. These children are referred to the foundation for study only after they have been certified by their family physician or pediatrician as being free from gross physical or mental defect and from behavioristic problems. No particular type of clinical examination is designated, but the physician is required to ascertain that the child is in a good state of organic health and shows no clinical evidence of metabolic defect. Roentgenographic studies with a view of bone age assessment are made as a routine at yearly intervals, or oftener if the child is under 5 years. X-ray films of six areas are made: the hand, elbow, shoulder, hip, knee and ankle. The majority of the files consulted showed at least four yearly studies entailing twenty-four x-ray films; a few had had seven studies a year or a total of forty-two films, and it was decidedly in the minority that there were only one or two studies a year. All areas are roentgenographed in the anteroposterior and lateral positions. An approximate total of 2,200 films was viewed.

Of the group reviewed only seven, or 7 per cent, showed evidence of chondro-epiphysitis.

At this time our studies are not sufficiently advanced to give any imposing factual data with regard to follow-up x-ray films after treatment. However, in eight cases so far studied a complete return to normal bone detail roentgenographically has been obtained by the administration of a fully tolerant and maintained dose of thyroid extract. Zuck[5] in 1933 reported that the restorative process could be hastened by endocrine therapy. That normality can result without treatment is readily admitted, as we are aware that not infrequently mild endocrine imbalances spontaneously correct themselves. It is suggested, however, that such x-ray evidence is a definite indication for thyroid therapy.

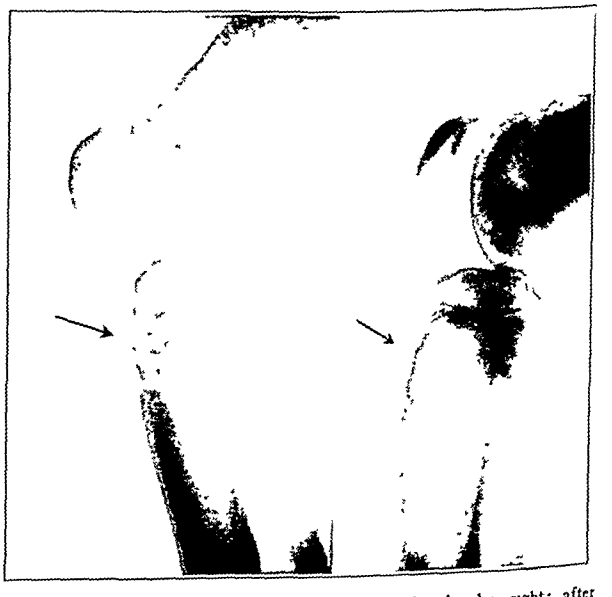

Fig. 2.—Left: chondro-epiphysitis of the tibial tubercle; right: after twelve months' treatment with thyroid extract at tolerance. Note improvement in the bony detail of the epiphysis and disappearance of the fragmentation and irregularity in both cases

CONCLUSION

1. A group of 258 endocrinopathic patients in an age range of 8 to 15 years was studied: ninety-one, or 35.2 per cent, displayed single or multiple evidence of chondro-epiphysitis; eighty-five of the ninety-one showed clinical or laboratory evidence of primary or secondary hypothyroidism.

3. Dr. C. L. Douglas of Detroit.
4. Aid was received from Mr. Howard H. Gradis, Dr. Todd's assistant.
5. Zuck, T. T.: J. Pediat. 3: 424-433 (Sept.) 1933.

2. A control group of ninety-nine nonendocrine patients in the same age range showed only seven, or 7 per cent, cases in which there was involvement of chondro-epiphysial structures.

3. Chondro-epiphysitis is of *endocrine origin*, specifically due to a primary or secondary hypothyroidism, usually asymptomatic and, to a degree, undoubtedly generalized.

4. Chondro-epiphysitis is a pathognomonic sign of hypothyroidism.

DIPHTHERIA IMMUNITY IN CHICAGO

HERMAN N. BUNDESEN, M.D., Sc.D.
President, Chicago Board of Health
WILLIAM I. FISHBEIN, M.D.
AND
JOHN L. WHITE, M.D.
CHICAGO

Although diphtheria mortality and morbidity have been gradually decreasing in most parts of the United States for the past twenty-five years, they have not been reduced to the level which it was hoped would be attained. Antitoxin, control of carriers and the Schick test were important. The discovery of toxoid added new impetus to the efforts to control this disease. It was believed that the inoculation of a large proportion of the child population would result in almost complete eradication of diphtheria.

The results obtained with the use of toxoid did not, however, approximate expectations. The present study explains to some extent this failure.

In Chicago, until 1931, three 1 cc. doses of antitoxin at weekly intervals were used for diphtheria immunization. In 1931 plain toxoid, two 1 cc. doses at weekly intervals, was employed. From 1932 to 1934 alum toxoid, two 1 cc. doses at weekly intervals, was used; from June 1934 to August 1934 a 1 cc. dose of alum precipitated toxoid was used; from Aug. 1, 1934, to January 1935, two 1 cc. doses of alum toxoid at weekly intervals were given; from January 1935 until late in 1936 a 1 cc. dose of alum precipitated toxoid was again used. Since that time we have employed three doses of plain toxoid given a month apart, the first dose 0.5 cc. and the other two doses 1 cc. each.

Before a change was made from one type of preparation to the other, experimental tests were carried out on groups of at least 1,000 children each. The children were inoculated with the various preparations, and Schick tests were made at intervals of from two to six months to determine whether protection against diphtheria had been obtained. In other words, the determination of the type of preparation to be used was based on the Schick testing of inoculated children, together with evidence obtained from similar studies carried out elsewhere.

Table 1 reveals that diphtheria mortality and morbidity reached a low level in 1933. After that time there was a gradual rise. The levels, however, did not nearly approach those of the years prior to 1933. The reduction in 1933 was the result of widespread inoculation with toxoid of children in the city of Chicago.[1] Since that time the number of inoculations each year have been at least 80 per cent of the number of children born.

We therefore believe that, as far as the number of children inoculated is concerned, we are taking the steps necessary to control diphtheria adequately. Failure to maintain the low rates of mortality and morbidity obtained in 1933 must consequently be ascribed to the fact either that inoculated children are not rendered immune or that if they do become immune this immunity is lost with the passage of varying intervals of time.

In order to determine what has been occurring with the groups of children inoculated with the various preparations employed in Chicago, a study was undertaken in 1936. Children inoculated with these different preparations were selected of as nearly the same age as possible. The ages at the time of testing varied generally between three and seven years. In the group that received toxin-antitoxin, the children were somewhat older, that is between 9 and 13 years. Those who received three doses of toxoid at monthly intervals for the most part were between 1 and 2 years of age. A record was kept of the intervals between the time the inoculation for the prevention of diphtheria was given and the time at which blood was drawn for the determination of the antitoxin content. Antitoxin titrations were determined by the Fraser modification of Romer's technic,[2] except that white guinea pigs were used instead of rabbits. The children were given a Schick test immediately after blood was drawn for the antitoxin determination. This was done because the Schick test in itself is known to stimulate the formation of antitoxin in the blood.

1934	327	41	1.2
1935	762	83	2.4
1936	614	87	2.5
1937	655	84	2.3

RESULTS

Group 1. The children in this group had received three injections of toxin-antitoxin a week apart during 1930. The children ranged in age from 3 to 7 years at the time of the injection, the majority being 5 years of age. The ages at the time the Schick tests were done ranged from 9 to 13 years. In the majority of

1. Bundesen, H. N.; Fishbein, W. I., and Niblack, H. C.: Diphtheria Control in Chicago, J. A. M. A. **100**: 1093 (April 8) 1933.

2. Fraser, D. T.: Tr. Roy. Soc. Canada (Sect. V, Biol. Sc.) **25**: 175 (May) 1931.

instances the blood was drawn and the Schick test done about six years after inoculations had been given.

The Schick tests gave negative results in all except two cases. Both of these children were 5 years of age at the time of the inoculation and 11 years of age at the time the Schick test was done. Thus, of 125 total children in the group, 123 showed negative Schick tests.

Table 2 shows the results of the antitoxin determination of these 123 Schick-negative children. Of the two children who showed positive Schick tests, one had less than 1/500 unit of antitoxin per cubic centimeter of blood, while the other had between 1/500 and 1/250 unit of antitoxin.

Group 2. This group was made up of children who had been given plain toxoid—two doses at weekly intervals—during 1932. The children were about 5 years of age at the time of inoculation and about 9 years of age at the time the blood was drawn and the Schick test done.

There were 125 children in this group; 106 were Schick negative and nineteen Schick positive. Of these nineteen Schick-positive children twelve had less than 1/500 unit of antitoxin per cubic centimeter of blood, four had between 1/500 and 1/250, two had between 1/250 and 1/100 and one had between 1/100 and 1/50.

Group 3. This group consisted of children who were given two doses of alum toxoid, not precipitated, one week apart. These children were inoculated between 1932 and 1934. Their average age at the time of inoculation was between 5 and 6 years. The blood was drawn and the Schick test done when the children were between 7 and 9 years of age.

Of these 145 children, sixteen showed positive Schick tests and 129 showed negative Schick tests. Of those who showed positive Schick tests, seven had less than 1/500 unit of antitoxin per cubic centimeter of blood and nine had between 1/500 and 1/250 unit. In table 2 under group 3 are the results of the antitoxin determination in the Schick-negative children.

Group 4. In this group there were 119 children, ranging in age from 5 to 7 years. This group had been given one dose of alum precipitated toxoid in 1934. Blood was drawn and Schick tests were done in 1936.

Of these 119 children, six showed positive Schick tests and 113 were negative. Of those who showed positive Schick tests, three had between 1/500 and 1/250 unit of antitoxin per cubic centimeter of blood, two had less than 1/500 and one had between 1/25 and 1/10. The antitoxin determinations and percentages of those who showed negative Schick reactions are seen under group 4 in table 2.

Group 5. In the latter part of 1936 and in 1937 a group of 107 children were given plain toxoid, three doses at monthly intervals. The ages of the children varied from 8 months to 2 years at the time of inoculation. Blood was drawn for antitoxin determination and the Schick test was done on this group in the early part of 1938, which was from one to one and one-half years after the inoculations were given.

In this entire group of 107 young children there were none who showed positive Schick test reactions—all were Schick negative. The antitoxin determination of these children can be seen under group 5 in table 2. Schick test studies were carried out on a large number of the children in each of the five groups during 1936, 1937 and 1938.

In group 1, in 1936 and 1937, Schick tests were done on a group of 583 children ranging in age from 10 to 15 years, who were given antitoxin, three doses a week apart, prior to 1931. Of this group of 583 children 546, or 93.6 per cent, showed negative Schick test reactions and thirty-seven, or 6.4 per cent, were positive.

In group 2, Schick tests were done on a total of 829 children ranging in age from 10 to 15 years, who had received two doses of plain toxoid one week apart in 1931 and 1932. Of these children 702, or 87.1 per cent, showed negative Schick test reactions and 127, or 12.9 per cent, positive.

In group 3, Schick tests were done in 1936 and 1937 on 634 children ranging in age from 7 to 9 years. These children received two doses of 0.2 per cent alum toxoid, not precipitated, one week apart in 1932 to 1934. Of these 514, or 81.1 per cent, showed negative Schick test reactions and 120, or 18.9 per cent, positive.

In group 4, a total of 660 children ranging in age from 1 to 4 years, were given one dose of alum precipitated toxoid in 1934. Of this group, in which Schick tests were done in 1936 and 1937, 612, or 92.7 per cent, showed negative results, and forty-eight, or 7.3 per cent, positive results.

In group 5, 1,000 children, or 100 per cent, of those tested, during 1938, ranging in age from 1 to 11 years, but for the most part from 1 to 2 years of age, responded negatively to the Schick test. This group was given plain toxoid, three doses a month apart, during 1936 and 1937.

COMMENT

Immunity to diphtheria may occur in various ways. It may be inherited, it may be acquired as a result of inoculation of some type of antigenic material or it may develop as a result of the inhalation of minimal

doses of diphtheria organisms. There is the possibility of "maturation immunity" or insusceptibility to disease due to maturity, independent of minimal inoculations.

In most children who are immune to the disease such immunity has probably developed as a result of all these factors. The inherited immunity is probably almost completely lost, in practically all cases, by the time the child has reached 1 year of age. Immunity that develops as the result of the inoculation of antigenic material lasts for a varying period of time, depending on the type of material inoculated and on the interval between doses. The longer the period after inoculation, the less should be the antitoxin content of the blood if these children are not exposed from time to time to diphtheria organisms, so that further immunity may develop as a result of the natural body processes.

In a consideration of the results which we have obtained in our experimental work, these various factors must be borne in mind. A greater interval elapsed between the time of inoculation and the time of testing in the children in group 1 than in the other groups. Hence from this standpoint it is to be expected that they would show lesser amounts of antitoxin. However, there was a greater opportunity for natural immunity to develop. Therefore an exact comparison is not possible between the children in the various groups. Nevertheless the figures seem to indicate that, both from the standpoint of the amount of antitoxin in the blood and from the standpoint of the Schick test, those children who received three doses of toxoid a month apart were better protected against diphtheria than those who received other types of inoculations. Just how long this immunity will continue cannot be stated at the present time. It is our intention to carry out further tests of the antitoxin content of the blood, from year to year, on the same group to determine the answer to this question.

Evaluation of the methods used to immunize the children in the five groups cannot be given with exactness till more time has passed and the relapse rate in group 5 can be determined. The observation may be made, however, that the time interval between immunization and the Schick test decreased by the integral variant of 1, while the percentage of relapses decreased by roughly 6 per cent a year from group 2 to group 5, giving an expected relapse rate in group 5 of zero, which it actually was. This does not make the results of a relapse rate of zero seem as good an omen of future high Schick negatives as may be expected from first examining the results. In fact, group 1, with a time lapse between immunization and Schick testing of six years and a relapse rate of only 2.4 per cent, has the statistical advantage over all other groups provided the important effect of environmental stimuli can be discounted.

Jensen [3] has experimentally shown that the rate at which antitoxin disappears from the blood is a function of a rectangular hyperbola: $Y = \frac{1}{X}$ or

$$T = \frac{A - X}{AX} \cdot \frac{1}{K}$$

A is maximum concentration of antitoxin following an antigenic stimulus, X is the amount of antitoxin which remains, T units of time after the moment at which A is reached, K is a constant which is different for each individual. This is the same formula by which lysins and other antibodies disappear from the blood.

3. Jensen, Claus: Deutsche med. Wchnschr. 57: 324 (Feb. 20) 1931.

One can see by the formula that when the amount of antitoxin is small the rate of decrease is small; i. e., if a patient has 1 unit of antitoxin per cubic centimeter of blood, his rate of loss of antitoxin is 10,000 times greater than when the antitoxin reaches 0.01 unit per cubic centimeter. If X or the antitoxin level is small and K is small, very long periods of time may elapse before an appreciable loss of antitoxin has been effected.

The toxin-antitoxin courses took place, however, at a time when the exposure to endemic diphtheria was much greater than could be experienced by the other groups; hence, so many of this first group encountered adequate secondary stimuli that the frequency of the Schick positive reactions decreased.

The main value of repeated doses of an antigen is that, should the antitoxin titer fail to rise within two or three days after the first inoculation it will not rise until the advent of a secondary stimulus.

The reasons given for failure to maintain the low rates of mortality and morbidity—that inoculated children are not rendered immune or that this immunity is lost with the passage of varying intervals of time—are ruled out by figures given in tables which show that

TABLE 3.—*Diphtheria Antitoxin Content of Blood in Inoculated Children*

the inoculated children are immune and that the immunity does last for a long period of time. Some other reason for this increase must be looked for.

The idea, backed by experimental proof, has been repeatedly put forward that the number of carriers of virulent diphtheria organisms is increased in proportion to the number of Schick negative persons in a community, and when a Schick positive is replaced by a Schick negative a potential avirulent carrier is replaced by a potential virulent carrier. Thus with a declining avirulent carrier rate goes a corresponding increase in the virulent carrier rate.

"Incomplete artificial immunization of a group may have no inhibitory effect on the total incidence of diphtheria and, for a short period, may increase the risk of attack in the unprotected section of the community." [4] The increased number of virulent carriers (gravis), coupled with the fact that an increased rate of relapses occurred in groups 2, 3 and 4, supposedly due to failure of the action of natural environmental stimuli, account in part at least for the upswing of diphtheria morbidity and mortality rates.

In the past, the Schick test has been relied on almost exclusively as an index of the immunization status against diphtheria. The Schick test is subject to some criticism. Presumably the test is negative when there is more than $\frac{1}{250}$ unit of antitoxin per cubic centimeter of blood.

4. Dudley, S. F.; May, P. M., and O'Flynn, J. A.: Special Report Series, No. 195, Medical Research Council, London, 1934.

It is interesting to note that fifty-nine of the 471 children in the first four groups studied had a negative Schick test with an antitoxin content of blood less than $\frac{1}{250}$ of a unit per cubic centimeter.

It has been stated that a child should have at least $\frac{1}{25}$ unit of antitoxin per cubic centimeter of blood to be relatively well protected against diphtheria. Hence the unreliability of the Schick test as the measure against diphtheria is indicated.

We find that, in group 1, 74 per cent of the children who received toxin-antitoxin had more than $\frac{1}{25}$ unit. In group 2, 63.2 per cent of the children who had received two doses of plain toxoid had more than this quantity. In group 3, 62.8 per cent of those who had received two doses of plain alum toxoid a week apart had more than this amount. In group 4, 43.4 per cent of the children who had received one dose of alum precipitated toxoid had more than this amount, while, in group 5, 89.7 per cent of the children who had received three doses of plain toxoid had more than $\frac{1}{25}$ unit of antitoxin per cubic centimeter of blood serum.

TABLE 4.—*Procedures Employed by One Hundred and Four State and City Health Departments*

Doses Employed	Number of City and State Health Departments
Alum Precipitated Toxoid (The dose varies from 0.5 to 1 cc.)	
1	58
2 (1 month apart)	9
2 (2 weeks apart)	8
2 (3 weeks apart)	2
2 (1 week apart)	1
2 (2 months apart)	1
2 (1 year apart)	1
Plain Toxoid (The dose varies from 0.5 to 1.5 cc., the usual dose being 1 cc.)	
2 (1 month apart)	10
2 (3 weeks apart)	9
2 (2 weeks apart)	5
3 (1 week apart)	5
3 (3 weeks apart)	5
3 (2 weeks apart)	3
3 (1 month apart)	3
Toxin Antitoxin (Employed in three doses a week apart in five city or state health departments)	

Of the methods of inoculation that have been employed in these five groups of children, it seems, from our figures, that without question the use of three doses of plain toxoid a month apart is the most efficient.

Further studies, however, will be necessary in order to determine the duration of such immunity as is acquired.

At present, according to the replies to a questionnaire which we sent to the health officers of many states and cities, there is great variation in the procedures employed in an attempt to produce immunity against diphtheria. Replies were received from 104 state and city health departments: thirty-six state and sixty-eight city. These replies indicated that thirty-seven cities employed alum precipitated toxoid almost exclusively, twenty-two employed plain toxoid almost exclusively, and seven employed both preparations, while two used both alum precipitated toxoid and toxin-antitoxin. The alum precipitated toxoid, according to these replies, is used more often than any type of antigen, the one dose method being employed by fifty-eight city and state health departments. The dose varied from 0.5 to 1 cc.

Table 4 indicates the number of health departments using alum precipitated toxoid, plain toxoid and toxin-antitoxin.

CONCLUSION

The evidence seems to indicate that more immunity to diphtheria is obtained when the antigen is given in a greater number of doses and the interval between inoculations is longer. Three doses of plain toxoid at monthly intervals seem to give the best result.

The Schick test cannot be relied on as a definite measure of the immunization status. The type of inoculations being used throughout the United States at present for the most part cannot be relied on to produce permanent immunity. With the adoption of three inoculations of toxoid at monthly intervals, it is to be hoped that diphtheria mortality and morbidity rates will show an even greater reduction in the future than they have in the past.

ADDENDUM

In March and April 1939, since the completion of this paper, seventy children in group 5 were retested to determine the antitoxic content of the blood and their reactions to the Schick test.

All the children were Schick negative. Thirty-eight, or 55.8 per cent, had more than $\frac{1}{10}$ unit of antitoxin per cubic centimeter of blood; seventeen, or 25.0 per cent, from $\frac{1}{25}$ to $\frac{1}{10}$; nine, or 13.2 per cent, from $\frac{1}{50}$ to $\frac{1}{25}$; three, or 4.4 per cent, from $\frac{1}{100}$ to $\frac{1}{50}$, and one, or 1.4 per cent, from $\frac{1}{250}$ to $\frac{1}{100}$. These figures represent a loss of 18.0 per cent in the group having more than $\frac{1}{10}$ unit, a gain of 9.1 per cent in those having from $\frac{1}{25}$ to $\frac{1}{10}$, a gain of 5.7 per cent in those having from $\frac{1}{50}$ to $\frac{1}{25}$, and of 3.5 per cent in those having from $\frac{1}{100}$ to $\frac{1}{50}$, with a loss of 0.4 per cent in those having from $\frac{1}{250}$ to $\frac{1}{100}$ unit.

These tests were carried out approximately two to two and one-half years following the administration of three doses of toxoid at intervals of one month.

Of the children who received three doses of plain toxoid at intervals of a month, 80.8 per cent have maintained, for a period of from two to two and one-half years, an antitoxic content above $\frac{1}{25}$ unit, which is the amount stated to be necessary for relatively good immunity against diphtheria. Thus in group 5 about 9 per cent of the children in a period of a year shifted from more than $\frac{1}{25}$ unit to less than this amount. At present none of this group have less than $\frac{1}{250}$ unit of antitoxin, which is the amount stated to be necessary to give a negative Schick test. These figures would indicate that with three doses of plain toxoid, given a month apart, immunity is relatively well maintained for a period of at least two to two and one-half years.

The children in this group probably have not had as great a possibility of coming in contact with diphtheria as those in the other groups. It seems evident, however, that this group of children must be retested yearly for the next several years before it will be possible to state definitely the rate at which immunity, as determined by the antitoxic content of the blood, is lost from year to year.

It is of interest to note that ten children of group 5 were retested in 1939 for their antitoxic content in addition to the seventy referred to. These ten, however, were Schick tested about three weeks prior to the drawing of blood for the antitoxin determination. Eight of these ten had more than $\frac{1}{10}$ unit in 1937; one had $\frac{1}{50}$ and the other $\frac{1}{25}$ unit. In 1939, after the Schick

test, eight showed more antitoxin than they had in 1937, one had the same amount, and one showed a slightly lesser amount.

Thus it seems from these figures that the stimulation of a Schick test in itself probably may be sufficient to increase the antitoxin content of the blood at least temporarily.

In view of the fact that there seems to be a gradual loss in the antitoxic content of the blood, consideration should be given to the advisability of reinoculating children with one dose of some antigen at intervals of from three to five years to maintain a sufficiently high level of antitoxin to ward off the disease.

GALLBLADDER DISEASE IN PATIENTS UNDER THIRTY YEARS OF AGE

CARL BEARSE, M.D.
BOSTON

While disease of the gallbladder occurs at any age, even in fetuses and newly born infants,[1] it is considered primarily a disease of middle age and later life.[2] Approximately 16.5[3] to 21[4] per cent of patients operated on for symptoms due to disease of the gallbladder are under 30. In an effort to determine the course of the disease before 30 and the end results following cholecystectomy, an analysis was made of sixty-three cases of operation performed during the first three decades of life. These cases represented 21 per cent of 300 consecutive cases in which I had performed the operation.

There were fifty-eight females and five males. The distribution by decades and by sex is shown in table 1.

The ratio of females to males was 12 to 1. This figure is much higher than the ratio for all ages, for which reported values have varied between 2.05 to 1[3] and 5.5 to 1.[5] In the group of 300 cases from which these sixty-three were selected, the ratio was 5.2 to 1. On the other hand, in a study limited to 432 children under 15 years of age[6] the ratio, while still in favor of females, was less than 2 to 1.

The general belief that a patient with disease of the gallbladder is usually overweight is not always borne out by the facts. Doran and his associates,[7] for example, reported that 53 per cent of their patients were overweight; Smithies,[3] on the other hand, reported but 8 per cent obese or consistently gaining weight. In the series of patients under consideration, twelve (19 per cent) were definitely overweight, forty-seven (74.6 per cent) were of average weight and four (6.3 per cent) were noticeably thin.

Since symptoms referable to the gallbladder occur frequently in relation to childbirth, it was not surprising that of the forty-eight married women in the series twenty-three (47.7 per cent) had symptoms either during pregnancy or shortly thereafter. In two cases the symptoms were so severe and persistent that operation was done during pregnancy; the pregnancy continued uneventfully. The remaining twenty-one patients deferred operation for at least two years, but all were operated on within five years of the onset of symptoms.

Acute infectious diseases, particularly typhoid fever and scarlet fever, have been frequently cited as etiologic factors in disease of the gallbladder. In this group thirty-five (55.5 per cent) gave a history of one or more infectious diseases. Twenty-eight patients had had measles, eight scarlet fever and four typhoid fever. Of the twenty-three patients with symptoms during pregnancy, only nine (39.1 per cent) gave a history of acute infection. This would imply that the likelihood of disease of the gallbladder in pregnant women is not increased by a previous infectious disease.

The symptoms were similar to those presented by older patients, such as pain in the area of the gallbladder at times radiating to the back and sometimes to the shoulders, and belching, nausea and vomiting. While pain was always the prominent symptom, in fifty cases (79.3 per cent) it was severe enough to be described as colic. In fourteen cases (22.2 per cent) it frequently occurred after eating. Only fifteen patients (23.8 per cent) complained of eructations, although belching was reported[8] as "prominent and distressing" in as many as 68.9 per cent of a group of patients of all ages. Nausea and vomiting affected twenty-nine (46 per cent), occurring almost as frequently as in older patients.

The symptoms varied in duration from twenty-four hours, when the patient was operated on after the first attack of colic, to twelve years in a patient of 29.

TABLE 1.—*Sex and Age by Decades*

Age (years)	Males	Females	Total

TABLE 2.—*Duration of Symptoms*

Years	Patients
Less than 1	19
1 to 2	18
2 to 3	16
4	5
5	3
More than 5	2

Table 2 shows the duration of symptoms for these sixty-three patients. The average duration for the entire group was 2.1 years and the average age was 24.7 years.

While only five patients (7.9 per cent) were operated on before the age of 20 (table 1) four additional patients, making a total of nine (14.2 per cent), had symptoms begining in their teens. Potter[6] collected from the literature 432 cases under the age of 15 years, and Starr[8] noted that 36 per cent of his patients had symptoms before the age of 25.

But five patients (7.9 per cent) showed evidence of clinical jaundice, and three of these (60 per cent) had no stones in the gallbladder. Blalock[9] pointed out that

jaundice was almost as common in patients of all ages with noncalculous cholecystitis as in patients with cholelithiasis.

Of the sixty-three gallbladders that were removed, four (6.3 per cent) were acutely inflamed and fifty-nine (93.6 per cent) showed chronic cholecystitis, including one with cholesterosis. Thirty-eight gallbladders with chronic inflammation (64 per cent) contained stones, and stones were also present in all but one of the acutely inflamed gallbladders. In other words, a total of forty-one gallbladders (65 per cent) had stones. One patient, a boy of 7 years, showed noncalculous acute cholecystitis.

Besides this 7 year old boy there were twenty-one patients with noncalculous cholecystitis; sixteen of these (76.1 per cent) had colicky pain. Other investigators [10] have reported that approximately 55 per cent of their patients with noncalculous chronic cholecystitis gave a history of colic.

Eight common ducts (12.6 per cent) were opened and, together with the hepatic ducts, explored. Only three common ducts (37.5 per cent) contained stones. The patients with choledocholithiasis had no jaundice at any time. They were 24, 27 and 29 years old. The shortest duration of the disease was four years, in the 24 year old patient. Symptoms were present for five years in the 29 year old patient and for seven years in the 27 year old patient.

The incidence of stones in the common duct in the entire series was 4.7 per cent, but for the forty-one cases of calculous gallbladder the incidence was 7.3 per cent. It has been reported that in only 4 per cent of cases of noncalculous gallbladder are stones found in the common duct.[11] In the twenty-one instances of noncalculous gallbladder in this series no stones were present in the biliary ducts.

TABLE 3.—*Comparison of End Results*

Author	Cured or Improved: With Stones, %	Cured or Improved: Without Stones, %
Present study (patients under 30)	97.2	85.0
Wilson, Lehman and Goodwin [9]	79.0	64.0
Kunath (J. A. M. A. **109**: 183 [July 17] 1937)	84.3	69.0
Graham, E. A., and Mackey, W. A. (J. A. M. A. **103**: 1497 [Nov. 17] 1934)	....	65.2
Brown, M. J. (Am. J. Surg. **41**: 238 [Aug.] 1938)	....	70.8

Stones are not rare in the common and in the hepatic duct of patients under 30. Of 221 patients with stones in the biliary ducts, fifteen (7.4 per cent) were under 30.[11] Moreover, of 226 patients under 15 with disease of the gallbladder, thirteen (5.7 per cent) had stones in the biliary ducts, including an 8 month fetus and two infants of 12 and of 25 days.[12] On the other hand, the incidence of stones in the common and in the hepatic duct of patients of all ages has been reported as high as 21.2 per cent.[11]

One patient in this group had acute hemorrhagic pancreatitis associated with cholelithiasis. She was an obese woman 29 years old who had had symptoms for three years before operation.

There were no deaths in this series.

Only four patients had any postoperative complications. One patient had phlebitis, which kept her in the hospital thirty-four days; she had had a similar complication following childbirth three years previous to operation. One patient had a superficial infection of the operative wound, which cleared up in several days. Another patient, aged 29 years, whose common duct was opened and explored and the sphincter of Oddi dilated, had a gas bacillus infection. The infection was not severe and she was discharged from the hospital as "well" on the twenty-first postoperative day.

It was possible to follow fifty-seven patients (90.4 per cent) after operation. Twenty-four patients were followed from one to four years, fifteen were seen from five to eight years after cholecystectomy and eighteen were followed from eight to ten years or more. The longest period of observation was thirteen years.

Fifty-three patients (92.9 per cent) were free from symptoms when last seen. Thirty-six (97.2 per cent) of the thirty-seven who had gallstones were entirely relieved; seventeen (85 per cent) of the twenty who had noncalculous chronic cholecystitis were either greatly improved or completely relieved. These satisfactory end results were much better than those reported for patients of unclassified age groups (table 3). In the reports for cholelithiasis the improvement varied from almost 3 to 18 per cent, while for noncalculous cholecystitis the improvement ranged from 14 to 21 per cent.

Four patients (7 per cent) had attacks of gallbladder colic following cholecystectomy. One of these patients had cholelithiasis and three had noncalculous cholecystitis. The pain was severe enough in two cases to warrant repeated hypodermic injections of morphine by the family physician. At no time did any of these patients have jaundice, chills or fever. X-ray examination showed no abnormality. Whether these postoperative attacks of colic were due to overlooked stones in the common duct, to biliary dyskinesia or to some extrabiliary abnormality is problematic.

One patient who was considered cured was free from symptoms for two years after removal of a noncalculous gallbladder. Then the attacks recurred and persisted for three years. Because nonsurgical treatment gave no relief, another operation was done; only adhesions were found. Since then she has been free from all symptoms.

In any group of patients with a noncalculous gallbladder the question may be raised whether operation is justified, in view of the large percentage that are unrelieved. Blackford and his associates [13] followed 200 patients of all ages with noncalculous chronic cholecystitis for from five to fifteen years. They reported that but 37 per cent had satisfactory relief without operation for more than eight years; 48 per cent who had nonsurgical treatment for the same period either were operated on later or should have been, because of persistence of symptoms.

SUMMARY

Sixty-three patients operated on for disease of the gallbladder before the age of 30 represented 21 per cent of 300 consecutive cholecystectomies.

Operation before the age of 30 does not mean that the disease is necessarily of short duration; five patients

(7.9 per cent) had symptoms for five or more years and one had symptoms for twelve years.

Only four patients (6.3 per cent) had acute cholecystitis and fifty-nine patients (93.6 per cent) had chronic cholecystitis. Gallstones were present in forty-one cases (65 per cent); this included three of acute cholecystitis.

Three patients had stones in the common duct, an incidence of 4.7 per cent, but when the incidence was based on the forty-one cases of calculous gallbladder it was 7.3 per cent. The duration of the symptoms in these cases varied from four to seven years.

Fifty-seven patients (90.4 per cent) were followed after operation; fifty-three (92.9 per cent) were free from symptoms when last seen. Thirty-six patients (97.2 per cent) of thirty-seven with cholelithiasis were entirely relieved; seventeen of twenty with noncalculous chronic cholecystitis (85 per cent) were either greatly improved or completely relieved.

TREATMENT OF VULVOVAGINITIS WITH ESTROGEN

CHARLES MAZER, M.D.
AND
FRED R. SHECHTER, M.D.
PHILADELPHIA

Infections of the immature vagina present a social and medical problem of considerable magnitude, especially in hospitals and asylums for children. Despite the available diagnostic procedures, it is often most difficult to differentiate the transmissible (gonococcic) from the nonspecific form of vulvovaginitis. It therefore becomes imperative to isolate at considerable cost and inconvenience every institutional case of vulvovaginitis. The occurrence of gonococcic vulvovaginitis in the home of a family presents no less a problem in preventing the spread of the infection to young sisters and schoolmates. In many instances the condition remains unrecognized until two or more members of a family are affected.

Although serious complications such as arthritis, salpingitis and ophthalmia are relatively infrequent, unless the gonococcus assumes an unusual virulence in passing through one or more susceptible hosts even the mild form of the infection leaves its imprint on the psyche of the affected child. The persistence of vulvar irritation for many months or years centers the attention of the growing child on the generative organs and often leads to the habit of masturbation and premature heterosexual inclinations.

The incidence of gonococcic vulvovaginitis varies with the facilities of the community to detect and isolate infected children lacking proper supervision. Taussig [1] found that 5 per cent of the girls attending the dispensary of the St. Louis Children's Hospital had gonococcic vaginitis and that in most instances the parents or guardians were unaware of its existence. Compulsory reporting of cases to health authorities, education of parents in prophylaxis and better nursing facilities in hospitals have tended in recent years to decrease the incidence of the infection in most communities.

From the Philadelphia Institute for Medical Research in the Philadelphia General Hospital.

ETIOLOGY OF VULVOVAGINITIS

Although the poor resistance of the ill child, as seen in the exanthems and in severe infections of the upper respiratory tract, plays an important role in the predisposition to vulvovaginitis, the most important predisposing factor is undoubtedly the low resistance of the immature vagina to any pathogenic bacteria, especially the gonococcus, which thrives in the alkaline medium occasioned by the glycogen-poor vaginal epithelium of the child.

The immature vagina, though not a sterile cavity, is zealously guarded against gross contamination and traumatism by the hymen until sexual maturity. Often the inexperienced nurse or intern, in making the routine vaginal smear preliminary to admission to the hospital, inadvertently brings the cotton swab into contact with the unclean external parts before the vagina is entered. This contamination plus the unavoidable friction-traumatism to the delicate vaginal epithelium frequently results in a nonspecific vaginitis, rendering the vagina more susceptible to invasion by the gonococcus. Such errors may be obviated, as suggested elsewhere by one of us,[2] by examining the centrifuged vaginal washings obtained through a small, soft rubber catheter after the vulva is thoroughly cleansed.

In institutional epidemics of gonococic vulvovaginitis the disease is most often transferred through the medium of diapers, bed linens, rectal thermometers or the hands of careless nurses. The nursing technic in a pediatric ward should be based always on the assumption that one of the patients has an unrecognized gonococcic vulvovaginitis. In most instances of vulvovaginitis occurring in the home of the patient, the source of infection may be traced to an infected member of the family or to a contaminated lavatory seat at home or in school. According to Taussig,[1] this is the most frequent mode of transmission of the disease because of the characteristic manner in which children slide from high toilet seats.

DIAGNOSIS OF VULVOVAGINITIS

The clinical picture of vulvovaginitis is unmistakable. To differentiate the transmissible (gonococcic) from other types of vulvovaginitis requires careful bacteriologic study by smear and culture. The demonstration of [illegible], intracellular diplococci, morphology of gonococci, is fairly reliable. Unfortunately the smear method has its limitations and, when negative or doubtful, the more refined culture method is essential to a differential diagnosis. The relative merits of the two diagnostic procedures in children presenting definite clinical symptoms of gonococcic vulvovaginitis were evaluated by Ruys [3] as follows: "Smears positive, culture positive in 111; smears negative, culture positive in fourteen; smears positive or doubtful, culture negative in seven." The superiority of the culture method was thus amply demonstrated. Since Micrococcus catarrhalis, frequently present in the vagina of children, morphologically resembles the gonococcus, the culture method is especially valuable in instances of positive smears without clinical symptoms. One must nevertheless remember that even the culture method is not infallible, since an overgrowth of secondary invaders may obscure the picture. Negative cultures under these conditions do

not preclude the possible presence of gonococci. The gonococcus complement fixation test, even with the improved technic employed by Mascall,[4] is positive in only 58.6 per cent of cases of gonococcic vulvovaginitis. It is therefore safer to consider every case of vulvovaginitis as gonococcic when discovered in a pediatric ward or an asylum for children.

PATHOLOGY OF GONOCOCCIC VULVOVAGINITIS

In the acute stage the vulva is reddened and edematous. When viewed through an endoscope the vaginal mucosa appears congested and the site of small erosions. The portio vaginalis in the vicinity of the pinhead sized external cervical os presents the same pathologic picture, giving the erroneous visual and bacteriologic impression of an associated endocervicitis. We agree with Schauffler and Kuhn [5] that the endocervix of the child is practically never invaded by the gonococcus because of the rudimentary state of its racemose glands. This also explains the singularly low incidence of salpingitis in children affected with gonococcic vaginitis. None of the 118 patients in this series showed clinical evidence of salpingitis, nor did one of us (Mazer) observe a single instance of this complication during the severest institutional epidemic of gonococcic vaginitis and arthritis in medical history, which occurred in one of the Philadelphia maternity hospitals in 1924.[6]

Bartholinitis is extremely rare. It was not encountered in any of our 118 patients. The urethral meatus is often red and pouting, but Skene's glands are rarely infected. However, the presence of pus cells in the urine voided following cleansing of the vulva points to an anterior urethritis, which was encountered by Miller [7] in six of sixty-eight cases of gonococcic vulvovaginitis. Only one of the 118 cases herein reported presented a definite urethritis.

Proctitis is apparently a frequent complication and may be a source of vaginal reinfection when untreated. The smear method is evidently inadequate to demonstrate involvement of the rectum. By means of a special culture medium, Ruys [8] recovered gonococci from the rectum in every child afflicted with specific vulvovaginitis. Clinical evidence of an associated proctitis is, however, rarely seen except during an institutional epidemic of the disease, when, as shown by Cooperman,[6] even the male infants show symptoms of proctitis.

Arthritis is rarely encountered except during epidemics, when the gonococcus assumes an unusual virulence in passing through many nonresistant hosts. Illustrative of this was the high incidence of gonococcic arthritis encountered during the Philadelphia epidemic, in which twenty-seven males and forty females were equally affected with gonococcic arthritis.[6]

BASIS OF TREATMENT OF VULVOVAGINITIS WITH ESTROGEN

Owing to the presence of maternal estrogen, the vaginal epithelium of the newborn is of considerable thickness (from thirty to forty layers of cells). The numerous basal layers are compact and irregular, forming papillae which penetrate deeply the tunica propria. Superimposed on the basal epithelium are many layers of spindle-shaped, glycogen-containing cells. The vaginal secretion is acid and the bacterial flora predominantly of the bacillary type.[9] Thus the safeguards present at birth are similar to those current in the mature vagina, which is so highly resistant to infections other than Trichomonas vaginalis. Within three or four weeks after birth, when the influence of maternal estrogen subsides, the numerous layers of glycogen-containing epithelial cells are thrown off and the basal zone becomes thin and regular in outline—evidence of inactivity. There is a paucity in cell glycogen and of Döderlein's bacilli, resulting in alkalinity of the vaginal secretions.[10] The vagina remains in this vulnerable state throughout childhood until the advent of puberty, when the estrogen elaborated by the maturing ovaries causes a return of the vaginal mucosa to a neonatal-like state, varying only slightly in structure during the cyclic changes in production of estrogen by the active ovaries. With the advent of senility, the vaginal epithelium once again reverts to that resembling immaturity, becoming even more vulnerable to infection and traumatism than the childhood vaginal epithelium. The superficial layers disappear, leaving only about six layers of small nucleated cells with a granular cytoplasm.[11]

Knowledge of these facts led Lewis [12] to employ injections of estrogenic substances in the treatment of gonococcic vulvovaginitis in the hope of transforming the vulnerable childhood vagina to the resistant adult types. The new treatment suggested by Lewis evoked considerable discussion in the medical literature, some favorable and some entirely unfavorable.

In employing a new product in the treatment of human ailments, its safety must be established first. The most valid objection to the use of estrogen in children is the possibility of permanent damage to the ovaries. This objection, based on the experimental observation [13] that prolonged treatment with estrogen produces regressive ovarian changes, is difficult to substantiate in human beings. Very few of the children treated with estrogen for gonococcic vaginitis have to date attained puberty. None have attained the age of childbearing, to permit determination of the effect of the hormone on germ plasm.

In defense of the use of estrogen, the following evidence of its safety is available:

1. Rats and monkeys given considerable quantities of estrogen for a relatively long period ultimately become estrous, mate and reproduce normally.[14]

2. The blood of the unborn infant is normally surcharged with estrogen to a degree (at least 1 mouse unit per cubic centimeter) far greater than that of children treated with maximum doses of the substance.

3. The few treated children who have already attained puberty have menstruated at the predicted age.[15]

4. Regularly menstruating women who receive estrogen in doses of 10,000 rat units every fourth day for periods varying from two to four months menstruate normally after withdrawal of treatment and bear normal offspring.[16] The more recent employment of vaginal suppositories, requiring, as it does, relatively small doses of estrogen, has partly solved the problem of possible harmful effects.

Next in importance to the safety of treatment of specific vaginitis with estrogen is its comparative effectiveness. Does it accomplish a cure sooner than other methods of treatment? Is the cure permanent or temporary? Opinions of competent clinicians concerning this phase of the problem differ so widely that, for the present, one must rely solely on personal experience. Dosage, length of treatment, mode of administration, attention to extragenital foci of infection not influenced by the substance and the ability to eliminate extraneous sources of reinfection undoubtedly account for the discordant reports. Dosage and route of administration are indissolubly linked, since even a small fraction of the hypodermic dose of estrogen produces the desired hypertrophy of the vaginal mucosa when introduced directly into the vagina.[17] Employment of the small doses required for vaginal administration of the substance reduces the incidence of the undesirable, though temporary and harmless, effects, such as enlargement of the breasts and premature menstruation, often encountered with effective hypodermic doses. There are, nevertheless, definite objections to prolonged vaginal treatment of the child. In addition to requiring intelligent cooperation of the mother, who, despite her intelligence, may nevertheless inadvertently carry the infection to another member of the family, oft-repeated vaginal treatment of the child frequently creates the habit of masturbation and premature heterosexual inclinations.

The size of the dose is the determining factor in accomplishing a cure. The length of treatment determines the percentage of recurrences. The longer the period of treatment, the less the chance of recurrence. The dose must be sufficient to cornify the vaginal epithelium and to reduce the p_H of the vaginal secretions to a point below 6. Our experience has shown that the minimum effective hypodermic dose is 500 rat units given every other day. Smaller doses, such as 100 rat units (approximately 800 international units), even when administered daily, produce only doubtful vaginal reactions and require treatment for as long as twenty-two weeks.[18] The minimum dose by the vagina is 100 rat units nightly, inserted on retiring. With these doses, the necessary vaginal response (cornification, acidity and an absence of pus and gram-negative diplococci) is usually observed on the fourth week of treatment.

In considering the problem of dosage, it is pertinent to clarify the existing confusion which dual standardization of estrogenic products creates. Estrogenic substances vary widely in their ability to cornify the vaginal mucosa of the rat. The international unit (weight unit) of estrogen is 0.1 microgram. The rat unit (biologic unit) is the minimum quantity of estrogenic substance capable of evoking estrus in the castrated rat. The ratio between the international unit and the rat unit varies with the chemical composition and the purity of the product. In our laboratory, various samples of estrone (theelin) yielded 1 million rat units per gram, estriol (theelol) 150,000 rat units per gram, estradiol (progynon-DH) as much as 10 million rat units per gram, and estradiol benzoate (progynon-B) 5½ million rat units per gram. It is evident, therefore, that the use of the rat unit is preferable when dealing with the several estrogens.

Equal to the importance of dosage in accomplishing clinical and bacteriologic cure is the length of treatment in preventing recurrence of the infection. It will be seen later that the percentage of recurrences is larger when the period of treatment, despite early and repeated negative smears, is much less than eight weeks. We[15] have previously stressed the importance of the length of treatment in preventing recurrences. Lewis[18] is equally emphatic on this point. The truth of the dictum that too short a period of treatment and not reinfection is responsible for the majority of early recurrences is evident from a study of some of the available literature on hypodermic treatment of vulvovaginitis with estrogen. Regardless of dosage, which if inadequate could not have produced even a temporary cure, too short periods of treatment (from twenty-one to forty days) allowed recurrences in nine of twenty-two patients treated hypodermically by Te Linde,[19] in seven of thirteen treated by Phillips,[20] in four of eleven treated by Brown[21] and in eight of twenty-two children treated by Reichert.[22] On the other hand, with longer treatment (from fifty to sixty days), Limper[23] observed no recurrences in twenty-four patients discharged as cured, and Lewis[18] encountered none in twenty-two. Recurrences appearing soon after the vagina returns to its former immature state (four weeks after treatment) may be reasonably attributed to insufficient length of treatment and not to reinfection. Those appearing later than three months after withdrawal of treatment may be attributed to reinfection or to a persistent focus not within the influence of the substance.

EVALUATION OF TREATMENT WITH ESTROGEN IN 118 CASES OF GONORRHEAL VULVOVAGINITIS

The present study embraces a group of 118 children, ranging in age from 18 months to 11 years, admitted consecutively to the wards of the Philadelphia General Hospital from January 1935 to May 1937 for the treatment of gonococcic vulvovaginitis. The diagnosis in each case was based on clinical symptoms and on the presence of gram-negative, intracellular diplococci, structurally characteristic of the gonococcus in the vaginal smear. Since the children were hospitalized during the entire period of treatment, there was an excellent opportunity to observe the response to the administration of estrogen. About one third of the children were in the acute stage of the illness at the time of admission. The duration of the disease in the others ranged from two months to two years. There was

no appreciable difference in the response of the respective groups to treatment with estrogen.

Eighty-one of the 118 children were treated by means of hypodermic injections of estradiol benzoate (progynon-B [24]); thirty-four received the same product as vaginal suppositories, and the remaining three were given estradiol (progynon-DH) orally.

HYPODERMIC ADMINISTRATION OF ESTROGEN

Sixty-one of the eighty-one children hypodermically treated received from 1,000 to 1,500 rat units and seven were given 500 rat units every other day for eight weeks; the remaining thirteen received 500 rat units every other day for a period of from four to six weeks.

The first of four consecutive vaginal smears was obtained after two weeks of treatment in forty-six cases, in the fourth week of treatment in fourteen and during the fifth week in eighteen. The vaginal discharge was then scanty, thick and snow white, revealing a mass of non-nucleated epithelial cells and gram-negative bacilli on smears. In the remaining three the vaginal smears were persistently positive, possibly because of inadequate vaginal drainage of accumulated débris, which in itself may have been a source of irritation. In order to evaluate treatment with estrogen accurately, no attempt was made to dilate the introitus or to irrigate the vagina for the purpose of removing the plugs of desquamated epithelial cells.

Sixty-one of the seventy-eight children successfully treated with estrogen hypodermically were followed for a period of from three to twenty-three months, with an average of ten months for the entire group. There were only six (10 per cent) recurrences in the sixty-one followed-up patients who had received hypodermic treatment. Analyzing the sixty-one followed-up cases according to the length of treatment, we found four recurrences in the fifty-three who had received treatment for eight weeks and two in the eight who had received treatment for a period of only from four to six weeks. Notwithstanding the fact that the comparison is made on too few patients, it is nevertheless significant that the incidence of recurrences in the group of eight followed-up patients who had received the relatively short treatment was three times greater than in the group treated for the full period of eight weeks. Equally significant is the fact that recurrences with shorter treatment were not only more numerous but appeared much earlier (from four to six weeks after treatment), suggesting that incomplete cure was the cause of the trouble.

Side effects other than growth of pubic hair occur more frequently and are more intense with adequate hypodermic treatment than with vaginal suppositories. Twenty-one of the eighty-one children (26 per cent) showed enlargement of the breasts, which persisted for about a month after withdrawal of the treatment; seven (8.5 per cent) had a scanty growth of pubic hair, which eventually disappeared, and eight (10 per cent) had a single episode of uterine bleeding either during treatment or later.

TREATMENT WITH VAGINAL SUPPOSITORIES OF ESTROGEN

Thirty-four children were treated with vaginal suppositories, each containing 200 rat units of estradiol benzoate (progynon-B), inserted nightly on retiring for a period of eight weeks.

A clinical cure and four consecutive negative vaginal smears were obtained during the fourth week of treatment in thirty-three of the thirty-four children. The remaining patient failed to respond to vaginal as well as to subsequent hypodermic treatment with 1,500 rat units given every other day for a period of eight additional weeks.

The side effects with vaginal suppositories of estrogen were less pronounced than with hypodermic treatment. In eight of the thirty-four patients there was a moderate enlargement of the breasts; in six there was a semblance of pubic hair growth and in one a single episode of menstruation. This child was, moreover, 11 years old and might have menstruated irrespective of the treatment.

Twenty-six of the thirty-three children treated with vaginal suppositories and discharged as cured were followed for a period of from three to thirteen months, averaging seven months. There were no recurrences, essentially substantiating the observation of Te Linde [19] that the treatment of gonococcic vulvovaginitis with vaginal suppositories is practically free from recurrences. He [25] states that a check-up of his first 100 patients treated by vaginal suppository showed ninety-eight of them clinically well and with negative smears from three months to two and one-half years after the last treatment.

ORAL TREATMENT

In three patients, oral administration of 1,500 rat units daily of estradiol (progynon-DH) for a period of eight weeks failed to accomplish a cure. They were subsequently treated by other methods. These results with oral therapy are in accord with those obtained by Te Linde [19] in six patients treated with equally large doses for a period averaging 105 days. It seems that in the human being as well as in the experimental animal [26] the minimum effective oral dose of estrogen must be five times greater than the hypodermic dose.

SUMMARY

1. The basis of treatment of vulvovaginitis with estrogen is the ability of the substance to create a temporary maturity environment in the vagina of the child and thus render it resistant to pathogenic bacteria.

2. The dose of estrogen must be sufficient to cornify the vaginal epithelium and to reduce the p_H of the vaginal secretions to a point below 6.

3. Treatment for eight weeks, despite an earlier clinical and bacteriologic cure, is a safeguard against recurrence of the infection.

4. Hypodermic injections produced a clinical and bacteriologic cure in seventy-eight of eighty-one children, with a 10 per cent incidence of recurrence.

5. Treatment with vaginal suppositories of estrogen produced a clinical and bacteriologic cure in thirty-three of thirty-four children without any recurrence in the twenty-six who were observed for a relatively long time.

6. Oral treatment was ineffective in three children who received as much as 1,500 rat units daily for a period of eight weeks.

7. Side effects, such as growth of pubic hair, uterine bleeding and enlargement of the breasts, are temporary and are more frequently encountered with hypodermic than with local treatment with estrogen.

LOCAL AND SYSTEMIC EFFECTS FROM INHALATION OF STRONG SOLUTIONS OF EPINEPHRINE

Inhalation of vaporized 1 per cent solution of epinephrine is extensively used in the relief of bronchial asthma.[1] This is a convenient way of obtaining directly the well known bronchodilator action of epinephrine without the necessity of hypodermic injection. The clinical results have been generally good as to relief of asthmatic attacks. At least ten atomizers are advertized as specially designed for this purpose, and, in addition, 1 per cent solution of epinephrine is the active ingredient of a large number of trade-marked antiasthma products offered to the public. In spite of the widespread use of this strong concentration of epinephrine, no reports have been made as to possible local irritative effects on the respiratory tract. When it is remembered that deep inhalations of this potent drug are practiced almost indefinitely in a chronic disease state, it would appear desirable to understand more fully and definitely, if possible, the mechanism of the antiasthmatic action and the possible side actions locally and systemically. Therefore, studies were initiated toward these ends and are reported in this paper.

SIZE OF DOSE

The vaporizers ordinarily used are specially designed to throw out very fine impalpable droplets, which are so small that they will not wet or fog a mirror. In order to determine how much of the solution was vaporized under conditions of ordinary use, three hand atomizers, or nebulizers, of the type prescribed for epinephrine inhalations were weighed on an analytic balance before and after use on ten different occasions. After squeezing the bulb forty times, which is more than is commonly done by patients, there was delivered an average of 0.034 Gm. of the 1 per cent solution, or 0.34 mg. of epinephrine from the mouth of the nebulizer, or about 0.008 mg. of epinephrine per compression. Only a small portion of this solution reaches the bronchi when the vapor is inhaled through the mouth. Spoto [2] working with dogs and Rubow [3] with rabbits estimated the penetration of such nebulized fluids into the deep respiratory passages by using solutions of chemicals which could be quantitatively determined in the lung tissue. They found that not more than 3 per cent of inhaled vapor reached the lung, and generally the amounts were much less. According to these authors the greater part of the solution was deposited on the pharynx, larynx and trachea.

Similar localization was confirmed for patients by the following observation:[4] A surgical patient, with a bronchial fistula in the anterior wall of the chest communicating with the left main bronchus, was prepared for excision of the fistula. A 5 per cent aqueous solution of gentian violet was continuously vaporized into the patient's mouth for several minutes while he inhaled deeply and exhaled through the fistula. A small catheter in the fistula conducted the expired air through a test tube of water, but this remained uncolored. The operation then proceeded, with excision of the fistulous tract. Examination of it immediately after removal failed to reveal the slighest trace of staining of the tissue by the gentian violet, although a blue color was present in

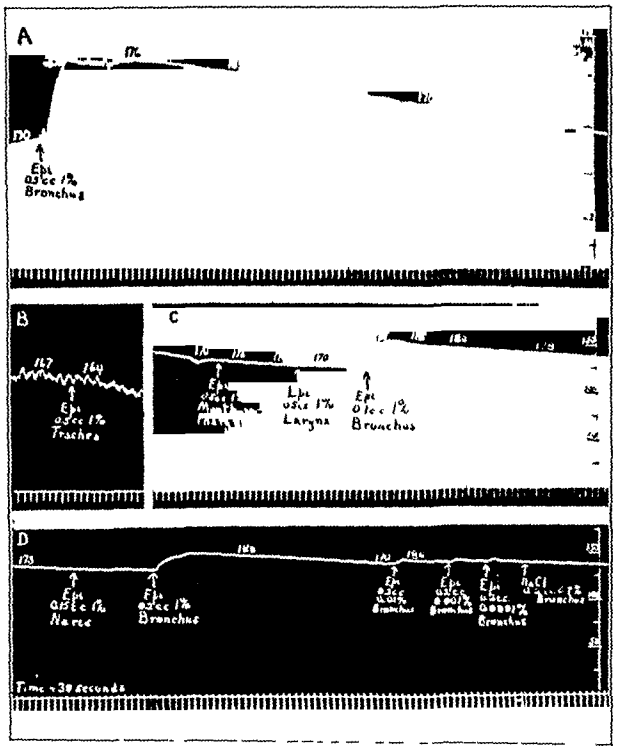

FIG. 1.—Effects on the blood pressure of a cat from different volumes and strengths of solution of epinephrine applied to isolated segments of the respiratory tract (pentobarbital anesthesia).

the mouth and posterior portion of the pharynx. Obviously not enough gentian violet reached the bronchus to impart a color to the water or to stain the walls of the fistula. From the fact that the tinctorial capacity of aqueous solutions of gentian violet is very great, a definite color being present in dilutions as low as 1:10,000,000, the total amount of the dye in the air expired must have been negligible. The mechanisms for removing particulate matter from the inspired air must be extremely efficient, as practically all the droplets were removed from the air before it reached the smaller bronchi. This agrees with Spoto's and Rubow's observations that the greater part of a vaporized solution remains in the upper part of the respiratory passages. In view of this result, it was of interest to determine whether the epinephrine was absorbed from the upper part of the respiratory tract and exerted any systemic effects.

Supported, in part, by grant 320 from the Committee on Therapeutic Research, Council on Pharmacy and Chemistry, American Medical Association.

CIRCULATORY EFFECTS

To this end the pressor and cardiac effects of inhalation of epinephrine in twelve asthmatic patients and four normal persons were determined as a measure of systemic absorption. The patients were all accustomed to the use of the nebulizer and were tested during an acute asthmatic attack. Pulse rates and blood pressures

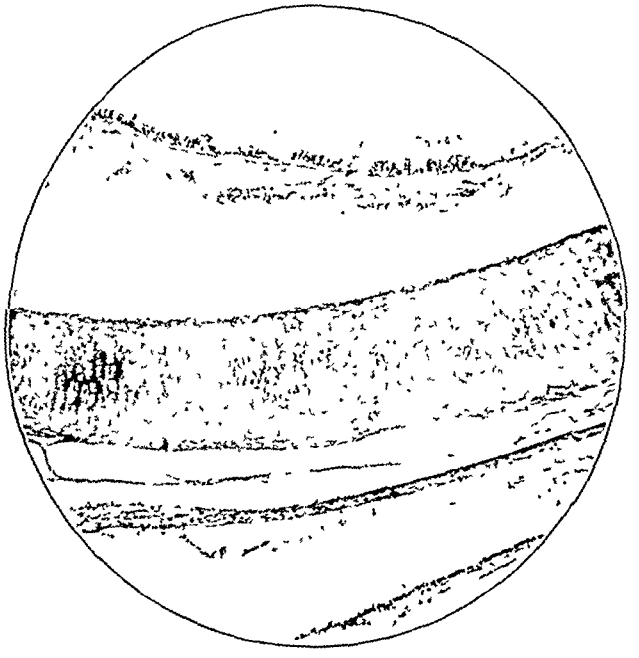

Fig. 2.—Microscopic section of trachea of cat after inhalation of 1 per cent solution of epinephrine, showing loss of cilia and desquamation of epithelium, together with beginning leukocytic infiltration of submucosa.

were determined every two minutes during ten minute periods before and during inhalation of the vapor and for ten minutes afterward. The administration consisted of ten deep inspirations with the nebulizer held just within the mouth. No changes in pulse rate or blood pressure were observed in either of the groups tested. Two of the normal persons noted subjective signs of palpitation and vertigo, but they were able to produce the same sensations by deep inhalations alone without epinephrine. These results are in general agreement with the clinical reports [1] and indicate that a systemic action of epinephrine under the conditions is not common.

Animal experiments were next made for more precise determinations of systemic effects under better controlled and more varied conditions. Cats anesthetized with intraperitoneal injection of pentobarbital sodium, 35 mg. per kilogram of body weight, were used. After tracheotomy, a section of the trachea was isolated by ligation from the larynx above and the bifurcation below in order to divide the respiratory tract into three parts, namely mouth and nasopharynx, trachea, and pulmonary or bronchial airways. Arterial blood pressure was measured by means of a cannula inserted into a common carotid artery and connected to a mercury manometer recording on a kymograph. The pulse rate was counted every five minutes or oftener.

The results of instilling different volumes of solution of epinephrine into these three regions are illustrated in figure 1. *No change in pulse rate or blood* pressure was recorded after instillation of such large doses as 5 mg. of epinephrine into the mouth, nasopharynx or isolated trachea. That is, typical systemic effects were not demonstrated after application to the mucosa above the bifurcation of the trachea. The bronchial mucosa, however, proved to be a good absorbing surface for epinephrine, since pulse and blood pressure changes were demonstrated after as little as 0.0002 mg. deposited in a bronchus. Considering the differences in body weight and the amounts lost in the upper air passages, a patient would require almost 100 inhalations to get an equivalent amount into his lungs and therefore to get systemic effects. This quantity could be obtained more readily, however, if compressed air were used for the vaporization, as is sometimes practiced in physicians' offices.

The failure to produce any effects from the excessive quantities applied to the tissue in the upper part of the respiratory tract makes it improbable that the solution deposited in this region is effective, acting either by reflex irritation or after absorption. In addition, the previous demonstration that to get systemic actions from the solution deposited deep in the lungs would require a much more prolonged period of inhalations than is ordinarily used for therapeutic effects makes it improbable that the effectiveness depends on getting enough absorbed in the lungs for a systemic action. Therefore the anti-asthmatic actions are probably the result of the direct local effects of the epinephrine on the congested bronchial mucosa and spastic musculature, occurring independently of absorption into the general circulation.

EFFECTS OF CHRONIC INHALATION

Repeated inhalations of this strong solution of epinephrine might be expected to cause local irritation and damage to the mucosa of the upper airways, since more

Fig. 3.—Microscopic section of trachea of cat after inhalation of 1 per cent solution of epinephrine. Ulceration of mucosa with loss of epithelium, marked leukocytic infiltration of submucosa and lumen filled with mucopus.

than 95 per cent of the inhaled solution is deposited in this region. Therefore ten cats and six rabbits were given the vapor for a determination of the local effects on the tissues. They were healthy animals, maintained on the standard diet of the laboratory colony. The animals were treated as follows: 1. Four rabbits and six cats were given inhalations of 1 per cent solution of epinephrine twice a day six days a week for a maxi-

mum of 121 days for the rabbits and seventy-one days for the cats. The dose was ten squeezes of the atomizer bulb or 0.0085 cc. of the solution of epinephrine delivered into the mouth as the vapor at each administration. 2. As controls, two cats and two rabbits inhaled at the same time an equal volume of physiologic solution of sodium chloride vaporized with a similar nebulizer. All inhalations were given through a mouth gag with the special nebulizer recommended for patients, and the jets of vapor were synchronized with the animals' inspiration in the same manner as is practiced by patients. 3. Because Graeser and Rowe and others [1] have reported gastrointestinal upsets in patients using epinephrine by inhalation, which they ascribed to swallowing the larger droplets, two cats were made to drink 1 cc. of 1 per cent solution of epinephrine six times each week. This was continued for twenty-two days with one cat; the other cat died on the seventh day. Histologic sections were made from the respiratory tracts of all the animals dying during the course of the experiment or killed at the conclusion of the medication. The accompanying table summarizes the histologic changes observed.

The most frequent abnormality was the presence of mucopus in the lumens of the bronchi. This occurred in seven of the ten animals receiving inhalations of epinephrine and in three of the six controls. The significance of this exudation is doubtful. More significant was the change illustrated in figure 2 of loss of tracheal cilia in six of the medicated animals and desquamation of tracheal and bronchial epithelium in four. These changes were not observed in any of the controls. In three of the epinephrine-sprayed animals there was a leukocytic infiltration of the tracheal submucosa which was sufficiently generalized to be termed a tracheitis, as shown in figure 3. Two cats from this group also showed evidence of bronchitis. These inflammatory reactions were not seen in the unmedicated controls. Five of the ten animals taking inhalations of epinephrine died during the course of the experiments after an average of thirty-seven days, the animals that remained being killed after an average of eighty-seven days.

Both of the animals receiving solution of epinephrine by mouth showed evidence of severe diarrhea, marked anorexia and loss of body weight, as did also one of the cats receiving the inhalations of epinephrine. Postmortem examination of the intestinal serosa and peritoneum of these three cats indicated the presence of inflammation, and the gastrointestinal mucosa showed many small ulcerated and hemorrhagic areas. Accordingly, these applications of epinephrine produced the typical signs of local irritation in both pulmonary and gastrointestinal tissues.

The question might be raised whether similar effects might be produced in patients. It is obvious that the opportunity of examining the trachea and lungs of patients receiving inhalations of epinephrine for asthma would be comparatively rare. However, we had an opportunity of examining one patient with conditions which were confirmatory of the changes in the cats. The pertinent facts of this case may be presented, with the histologic pictures, as follows:

A man aged 60 with advanced pulmonary tuberculosis showed no clinical signs of tracheal or laryngeal involvement. Inhalations of 1 per cent solution of epinephrine were given every two hours for forty-eight hours before death. At autopsy, which was performed immediately, the trachea was reddened down to within a short distance above the bifurcation. Microscopic examination revealed marked leukocytic infiltration throughout the reddened area (fig. 4) and areas of complete loss of epithelium with leukocytic infiltration of submucosa (fig. 5). Special stains revealed no evidence of tuberculous processes in this region, and the larynx and the bronchi below the bifurcation were free of these acute inflammatory changes, or tuberculosis. The pathologic diagnosis at this part of the autopsy was acute tracheitis produced by the inhalations.

COMMENT

The amount of epinephrine obtained from a 1 per cent solution by proper vaporization for inhalation is considerably less than the usual dose with other methods of administration. A patient taking ten deep inhalations of the vapor from a hand atomizer receives not more than 0.08 mg. of epinephrine into his mouth. Only about one one-hundredth of this quantity gets down to the bronchioles, where it produces its therapeutic effects. The minimum intravenous dose of epinephrine required to produce just demonstrable systemic effects is of the order of 0.001 mg. per kilogram of body weight, or about 0.07 mg. for an average adult. Assuming that the total amount of vapor sprayed into the mouth reached the lung and was instantly and completely absorbed, the dose of epinephrine would be barely enough to produce a trace of action after systemic distribution. However, since not more than about one one-hundredth of the inhaled epinephrine vaporized

Pathologic Changes in Rabbits and Cats Given 1 per Cent Epinephrine or Physiologic Solution of Sodium Chloride Twice a Day by Inhalation or 1 per Cent Epinephrine by Mouth

Animal and Number	Fate	Bronchopneumonia	Bronchitis	Tracheitis	Mucopus in Lumen	Desquamation of Epithelium	Loss of Cilia	Comment

in the mouth gets to the lungs, it is improbable that enough would be absorbed for a circulatory action. Therefore it is not surprising that clinical pulse rate or blood pressure changes are usually not demonstrable after inhalation of epinephrine. Nielsen reached the same conclusion when he found the dose of epinephrine

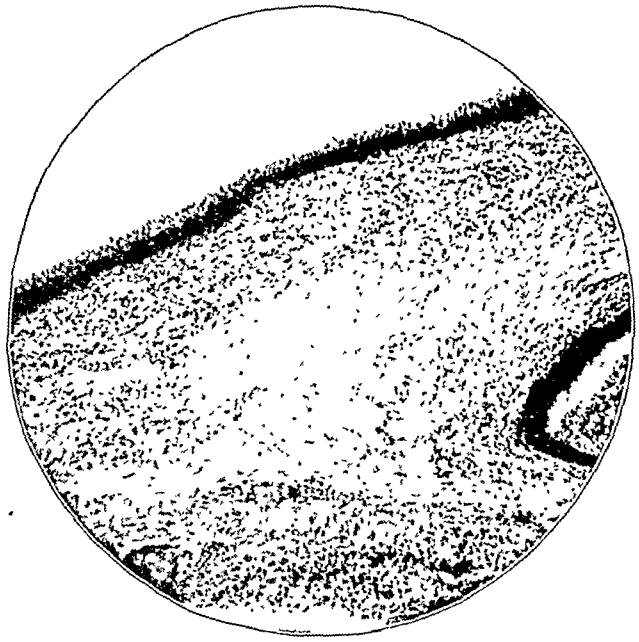

Fig. 4.—Microscopic section of tracheal mucosa of a patient who received inhalations of 1 per cent solution of epinephrine every two hours for forty-eight hours preceding death; marked leukocytic infiltration.

by inhalation to be considerably less than the systemic dose for an effect in the same patient. These results taken together indicate that the relief of asthmatic symptoms after inhalations of epinephrine is the result of a local or direct action of the epinephrine on the bronchial muscle or mucosa, the greater effectiveness for this condition being presumably due to the direct contact of the drug with the site of action.

As for the possible objectionable side actions from repeated inhalations of epinephrine, very definite pathologic changes were demonstrated by us in the respiratory tissues of some of the animals used and in the patient who had inhaled 1 per cent solution of epinephrine. In spite of the small total amount of epinephrine that is deposited on the mucosa, each droplet contains a very high concentration of the drug. It may be that the local irritant effect of each droplet is just as great for the point of deposition as that which would result from the application of a greater volume to a proportionately larger area.

The type of lesion observed in the tracheal and bronchial mucosae is in many ways similar to lesions produced by Fox[5] by spraying the nasal mucosa of rabbits with 1:1,000 solution of epinephrine hydrochloride. After daily applications for three months he found considerable denudation and intra-epithelial abscesses with leukocytic infiltration. The irritant power of even this ten times weaker solution is therefore well known for the nasal mucosa in animals as well as in patients. There can then be little doubt that a stronger solution, i. e. ten times, or the 1 per cent strength, would produce greater local irritation, as was indeed demonstrated by us.

5. Fox, Noah: Chronic Effect of Epinephrine and Ephedrine on Nasal Mucosa, Arch. Otolaryng. 13:73 (Jan.) 1931.

The solution of epinephrine used in our experiments, like many epinephrine products on the market, contains about 0.2 per cent sodium bisulfite to prevent oxidation of the drug. It has not been determined whether the irritation in the respiratory tract is due to the epinephrine itself, to the high acidity or to the preservative. In a recent publication, Tainter, Throndson and Lehman[6] described the irritant actions of sodium bisulfite on other mucous membranes. They showed that concentrations of this salt comparable to those in commercial epinephrine products were sufficient to produce local inflammatory reactions. However, the vasoconstriction probably contributes mainly to the local reaction, since it is well known that concentrations of epinephrine greater than 1:10,000 are apt to produce such prolonged vasoconstriction as to cause tissue damage from anoxemia with secondary inflammatory reactions.

Finally, there may be considered the bearing of these various observations on the clinical use of inhalations of epinephrine. There is no doubt that in many patients asthmatic attacks can be controlled by inhalation of strong solutions of epinephrine. There can also be little doubt that in some if not all patients the solution of epinephrine will produce inflammatory changes in the upper respiratory passages and possibly also in the gastrointestinal tract if droplets are swallowed. The more efficiently the patient breathes and draws the vapors into the deeper airways, the more extensive will be the inflammatory changes. If the concentration of the epinephrine should be increased from the 1 per cent strength now commonly employed to the 10 per cent strength advocated by Nielsen,[1] the possibility of local

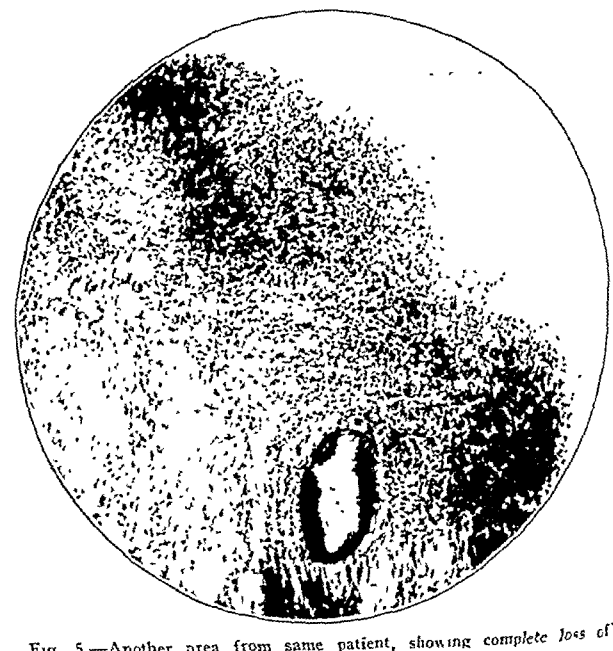

Fig. 5.—Another area from same patient, showing complete loss of epithelium and more marked round cell infiltration.

injurious effects would be still greater. The main reason for using the inhalation procedure is that it saves the patient the inconvenience of hypodermic injections. However, if this advantage is obtained at the expense of setting up inflammatory reactions in the mucosae of the respiratory passages, which are already the seat of a morbid process, the secondary effects of the inhalation

6. Tainter, M. L.; Throndson, A. H., and Lehman, A. J.: Proc. Soc. Exper. Biol. & Med. 36:584 (June) 1937.

may prevent or delay restoration of these tissues to normal, even though the spasmodic attack is alleviated. The clinician would therefore seem to be under the necessity of deciding in each individual case whether the gain in convenience of medication by inhalation is great enough to justify the possible production of added pathologic changes.

SUMMARY AND CONCLUSIONS

1. Epinephrine, in strengths of 1 per cent or more, is used extensively by inhalation in the treatment of asthma. This procedure introduces smaller quantities of the drug into the lung than those clinically effective by injection.

2. There is no demonstrable absorption of epinephrine from the respiratory tract in cats, except deep in the lungs. However, from the lungs, blood pressure effects can be produced from minute doses, indicating good absorption from the lower respiratory mucosa, and the possibility of producing direct effects by the drug on the bronchiolar muscle and mucosa.

3. Inhalation of 1 per cent solution of epinephrine at frequent intervals in cats and rabbits produces in some animals an irritation of the tracheal mucosa, with desquamation of the epithelium and inflammatory changes. Similar changes were observed in the trachea of a tuberculous patient similarly medicated for forty-eight hours before death.

4. Careful consideration should be given by the physician to the possible occurrence of undesirable local irritative effects from inhalations of epinephrine such as those demonstrated by us, and whether these are great enough in the individual patient to outweigh the convenience of taking the drug by inhalation rather than by injection.

ADENOCARCINOMA OF THE BREAST COINCIDENTAL WITH STRENUOUS ENDOCRINE THERAPY

G. R ALLABEN, M D, AND S E OWEN, PH D, HINES, ILL

Estrogenic substance induces mammary cancer in mice usually only after several months' application The carcinogenic agents likewise require considerable periods of application Injections of estrogenic substance or of carcinogenic chemicals in rather excessive doses may shorten the time of appearance of experimental tumors

The ordinary therapeutic doses of estrogenic substance and the rather short periods of treatment should not involve a risk of the subsequent development of cancer. A substitution therapy extending over many months does involve such a risk, especially if the woman treated presents a family history of mammary cancer and may thus supposedly be classed as susceptible

Cramer [1] has presented an excellent review of the etiology of mammary cancer in man and in mice. Olch [2] expressed the belief that prolonged ovarian activity during the usual menopausal ages is detrimental or of no benefit to the mammary parenchyma. Crossen and Hobbs [3] noted the high incidence of delayed menopause in cases of adenocarcinoma of the body of the uterus. Wassink's [4] statistical study on Dutch people showed that family history, as regards mammary cancer, was exceedingly important. Waaler's [5] observations in Norway lead to similar opinions Lacassagne [6] suggested that in experimental animals the hereditary factor for cancer of the breast may consist in an unequal response of the breast in the different strains to similar doses of estrogenic substances. Cramer [7] more recently demonstrated that mouse strains bearing a high incidence of cancer of the breast are more susceptible to estrogenic substance. It appears also from his work that the pituitary thyrotropic factor antagonizes the susceptibility to estrogen. A clinical investigation to determine if possible methods of identifying women who are unusually responsive to estrogenic agents is urgently needed. There is also much room for consideration of the family histories in the early diagnosis of mammary cancer.

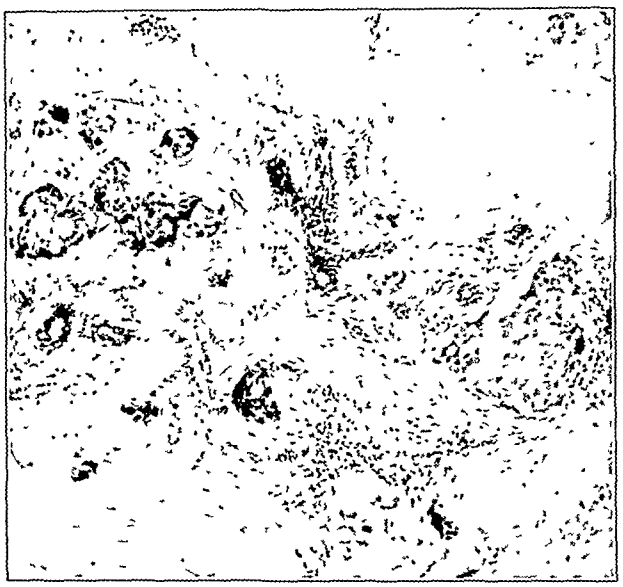

Fig 1.—Section of the original tumor, showing obliteration of the ducts and fibrosis

The following case is offered as an instance of what we believe to be an unwise use of estrogenic substance during the menopausal period. The adenocarcinoma of the breast in this instance, coincidental though it may be, tends to incriminate the heavy and prolonged estrogen treatment used:

REPORT OF CASE

History.—A white woman aged 50, a nurse, never married, entered the hospital in February 1938, complaining of a tumor mass in the right mammary gland, slightly painful and tender to pressure There had been no loss of weight The onset had occurred three weeks before admission to the hospital. While reaching to clean a wall of her home she had felt a pain in her right breast, and on examination she observed a lump which was tender to palpation. On consulting a physician she was referred to the hospital.

Menstruation began at the age of 11 years and continued regularly to the age of 48. In September 1936 she consulted a physician for symptoms of weakness and fatigue following

physical exertion. She was told that her blood pressure was low and was given estrogenic therapy, receiving 2,000 units intramuscularly twice a week for twenty-six weeks. At this time she consulted another physician, and this type of therapy was continued. She was given one injection of 10,000 units of estrogen and then 2,000 units three times a week for six months. During this time she did not menstruate, but occasional fulness of the breast was noted. In the fall of 1937, when she voluntarily stopped the injections, there was a copious menstrual flow lasting one week. There has been none since.

She had had measles, mumps and chickenpox in childhood and pneumonia at the age of 9 years and again at 20, with complete recovery. Tonsillectomy had been done in 1920. She had been admitted because of a mild depressive psychosis in March 1931 and discharged improved in July 1931. She was readmitted in October 1935, when an atypical mucous cyst of the lower lip was removed and hyperkeratosis of the left cheek was treated by superficial irradiation. She was discharged in November 1935, with maximum benefit. She had always been declared competent as to her psychosis, and at this time, although worried about her breast, she had good insight and judgment was not defective.

Her mother died at the age of 63 of carcinoma of the liver and her father at 72 of nephritis and cardiac disease. Five

Fig. 2.—Section of metastatic nodule.

brothers reached adulthood but had all died from various causes other than cancer. Four older married sisters had no history of cancer.

Examination.—The patient was well developed and somewhat obese. Her height was 67 inches (170 cm.) and her weight 186 pounds (84.4 Kg.). In the upper outer quadrant of the right breast a tumor mass 5 by 7 cm. in diameter was present. This was not attached to the deeper structures or to overlying skin. There was no retraction and no discharge from the nipple. No adenopathy was noted in the drainage areas. The left breast was apparently normal. General examination showed no further abnormality. The urine showed a trace of albumin and a moderate number of white blood cells. The Wassermann and the Kahn test were negative. A blood count was within normal limits. X-ray examination of the chest showed no abnormality.

Course.—Radical mastectomy was performed, with careful dissection of the axilla and removal of both pectoral muscles. A study of the removed specimen showed several small nodes just adjacent to the primary tumor. Microscopic examination showed adenocarcinoma in both the primary tumor and the metastatic nodes.

The patient received a full course of postoperative irradiation.

COMMENT

The total dose of estrogen (258,000 units injected) used in this case may not seem high. The therapy, however, was practically continuous for over a year. That no menstrual periods occurred in this interval rather substantiates the factor of continuous dosage, as do the prolonged menses when the treatment was discontinued. The patient's history indicates periodic if not rather constant stimulation of the breast during the period of therapy. This feeling of fulness in the breast was not noted after discontinuance of the estrogen therapy. There was but one instance of cancer in the family and that not cancer of the breast.

In our experience papillomas of the mammary duct similar to that noted in Schimmelbusch's disease may be induced in experimental animals in short periods with low doses of estrogen. More prolonged experimental treatment brings forth typical tumors of the breast. It is not our intent to generate cancerphobia or to discourage the correct therapeutic use of estrogenic preparations. We feel, however, that there is some question whether prolonged and continuous therapy, as in the case reported, is compatible with the normal physiologic endocrine balances. At the menopause nature is attempting to close a period and to readjust biologically the tissues concerned. Correct endocrine therapy should, it would seem, be planned to aid the natural physiologic procedures. Continuous estrogen therapy would maintain this agent at a high level in the body. A consistently high estrogen level is certainly unphysiologic as is evident from studies on estrogen excretion. More attention should be given to timing and to tapering off the doses of estrogen when this agent is employed for therapeutic effect during the menopausal period.

ANTERIOR POLIOMYELITIS TREATED WITH SULFAPYRIDINE

JOHN C. WAGNER, M.D., PONCA CITY, OKLA.

In view of the variation in the severity of the infection causing anterior poliomyelitis, with its differences in clinical picture, its symptomatology and its resulting paralysis, one case report is not of great value. The case here reported is interesting because the patient was seen during the acute stage and rather surprising results were had accompanying the use of sulfapyridine in the treatment.

History.—M. E. M., a well developed girl aged 9 years, weighing 65 pounds (29.5 Kg.), was first seen March 22, 1939, complaining of pain in the right leg and inability to walk without falling; onset had occurred two days before with fever, headache, pains in the back and legs, and general malaise.

Examination.—The temperature was 101, pulse 120, respiratory rate 20.

The skin, eyes, nose, throat, lungs, heart and abdomen were all entirely normal.

Examination of the right leg revealed the knee jerk reflex absent; the patient was unable to flex the thigh on the pelvis or flex the foot on the leg. Kernig's sign was positive. Oppenheim's and Babinski's signs were normal. There was no disturbance of sensation. Examination of the left leg revealed the knee jerk exaggerated. There was muscular tenderness throughout the thigh with normal flexion of the thigh on the pelvis and the foot on the leg. Kernig's sign was positive. Oppenheim's and Babinski's signs were normal or negative.

The patient was unable to stand on the right leg alone but could stand on both legs and walk with help with a slight dragging of the right foot and toe.

The arms, forearms and hands were normal. Function was good.

The posterior neck muscles were rigid and the patient was unable to flex the head on the chest without pain. There was no opisthotonos.

The pupils were of normal size and they reacted well to light and distance.

Ten cc. of clear spinal fluid was withdrawn; the pressure was slightly increased but returned to normal with this volume removed. Cell count in undiluted fluid was 100. Stained

smears showed 50 per cent polymorphonuclears and 50 per cent lymphocytes. No organisms were found with three Gram stains. Sugar was normal, a trace. Globulin was present with a heavy trace. Cultures were made on blood agar plates and reported at intervals of twelve, twenty-four, forty-eight and seventy-two hours.

The urine, March 23, was normal except for a slight trace of albumin. March 26 it was normal except for a slight trace of acetone. March 27 it was entirely normal.

March 23 there were 4,330,000 red blood cells, 85 per cent hemoglobin, 8,900 white blood cells, 64 per cent polymorphonuclears, 31 per cent lymphocytes, 4 per cent large mononuclears and 1 per cent basophils.

March 24 there were 4,210,000 red blood cells, 82 per cent hemoglobin, 9,750 white blood cells, 76 per cent polymorphonuclears, 29 per cent lymphocytes, 2 per cent large mononuclears and 1 per cent basophils.

March 25 there were 4,150,000 red blood cells, 82 per cent hemoglobin, 9,050 white blood cells, 70 per cent polymorphonuclears, 23 per cent lymphocytes, 5 per cent large mononuclears and 2 per cent basophils.

March 26 there were 4,150,000 red blood cells, 80 per cent hemoglobin, 6,450 white blood cells, 71 per cent polymorphonuclears, 22 per cent lymphocytes, 5 per cent large mononuclears and 2 per cent eosinophils.

March 27 there were 4,080,000 red blood cells, 80 per cent hemoglobin, 5,600 white blood cells, 70 per cent polymorphonuclears, 25 per cent lymphocytes, 4 per cent large mononuclears and 1 per cent eosinophils.

Treatment and Medication.—The patient entered the hospital March 22, 1939, at 9 p. m. The usual routine blood, urine and spinal puncture were done. Neoprontosil 15 grains (1 Gm.) every four hours for three doses was started at 11 p. m.

On the morning of March 23 examination was essentially the same as previously detailed, with the additional observation of toe drop with the foot extended and the thigh flexed on the pelvis on the right side, and paresthesias of both forearms and the little fingers of both hands. A molded plaster of paris splint was applied to the leg and foot at this time.

Sulfapyridine was started at 4 p. m., seven 7/10 grain tablets every two hours for twelve doses, at which time the temperature was 103.4 F., the pulse 130 and respiratory rate 28, with the blood picture 4,330,000 red blood cells, 85 per cent hemoglobin, 8,900 white blood cells, 64 per cent polymorphonuclears, 31 per cent lymphocytes, 4 per cent large mononuclears and 1 per cent basophils. The temperature returned to normal and remained so for twelve hours. The drug was temporarily discontinued, because the patient was slightly cyanotic and increasingly irritable, with anorexia, but was again started when the temperature returned to 100, in the same dosage, every three hours for six more doses. The temperature again returned to normal for a twelve hour period; the drug was discontinued, and the temperature returned to 99 for a two hour period only twice since sulfapyridine was stopped, and has been normal or subnormal for the past five days. The change in the blood picture with regard to giving sulfapyridine was as follows: March 23, 4,330,000 red blood cells, 8,900 white blood cells, 85 per cent hemoglobin. March 27, 4,080,000 red blood cells, 5,600 white blood cells, 80 per cent hemoglobin. The kidney function and urine were essentially normal at the onset and no untoward effects were noticed with the treatment. The slight rigidity of the neck muscles rapidly disappeared. The spinal fluid showed no growth on culture at twelve, twenty-four, forty-eight and seventy-two hours. The patient's general condition has satisfactorily improved. There is no further muscular paralysis than was present at the first visit, which was the third day after onset. The right leg and foot from the hip is in a molded splint, with no deformity, and the neurologic manifestations on this side are still an absent knee jerk and inability to flex the thigh on the pelvis or flex the foot on the leg.

CONCLUSIONS

This case could have terminated as it has in paralysis of the flexor muscles of the foot, leg and thigh of the right side without the use of sulfapyridine and not be unusual in any way; others have done it; but (1) the apparent dramatic response of the white blood cell count, (2) the drop in temperature from 104.5 to normal in twenty-four hours, remaining so for twelve hours and again responding to medication the second time, with continued approach to normal of the white blood cell count, and (3) the relief of the paresthesias, all so closely following the administration of sulfapyridine, leave us to determine whether this drug has a virtue in anterior poliomyelitis.

Take the report for what it is worth, but further use, properly given, is certainly justified in such cases, especially in patients seen early in the disease, as this case shows. I do not make the slightest claim of sulfapyridine being specific, having only a lingering hope for the future.

HEMORRHAGIC MUCOCELE OF THE APPENDIX

THOMAS F. HEATLEY, M.D., TOLEDO, OHIO

V. R., a high school girl aged 16, was admitted to the hospital Aug. 10, 1935. She had been in good health except for what she termed minor attacks of indigestion intermittently during the past two years. The attacks were never serious enough for her to consult her physician. On the morning of August 9 after arising she was taken with a dull aching pain in the right lower quadrant of the abdomen which did not radiate. The patient suffered profound nausea and vomited seven times during the day. There was no history of constipation and her menstrual periods were regular.

On admission to the hospital the patient's temperature was 100 F., the pulse 110 and the leukocyte count, 30,700. There was a definite palpable tumor mass in the right lower quadrant of the abdomen, exquisite tenderness over McBurney's point and an early peritoneal reflex. There was no abdominal distention; the last menstrual period had been normal and within ten days. A diagnosis of ovarian tumor with twisted pedicle was made and immediate operation advised.

Mucocele after removal, showing its tremendous size as compared with the appendix and its position lateral to the appendix.

Under ether anesthesia the abdomen was opened through a right paramesial incision and a tumor was exposed in the right iliac fossa. The tumor was entirely free of adhesions. The gallbladder and stomach and both kidneys were normal and there was no obstruction of the bowel. This tumor was dark in color and shaped like a cucumber. The appendix appeared to lie at its distal end and was attached approximately an inch from the junction of the appendix to the caput coli. The apparent pedicle was twisted about 120 degrees, and this whole mass was gangrenous. The tumor was removed from the appendix and the appendix was removed in the routine manner without drainage.

Convalescence was without incident and the patient was discharged in good condition on the eleventh postoperative day.

The gross appearance demonstrated a large, soft tumor with a thin, connective tissue wall almost bisected, thus forming two lobes filled with coagulated blood. The tumor was attached to the appendix. Section was made of the thin wall. The appendix, 6.5 cm. by 1 cm. at the proximal end, tapered to 6 mm. at the tip; the tumor was attached to the proximal portion by a small pedicle.

The microscopic section of the cyst wall filled with blood and showed hemorrhagic mucosa supporting only a few mucous glands, which showed hemorrhage into their lumens; the solitary follicles were enlarged, the lymphoid cells being pushed apart by edema and hemorrhage. The submucosa was edematous, its blood vessels were enlarged and congested and there was a large amount of hemorrhage into this coat; the muscular

Dr. Warren Howard permitted me to publish a report of this case. Dr. James B. Rucker gave his cooperation in the interpretation of the pathologic picture and Dr. George W. Bascom reviewed the literature.

coats were normal in thickness but were infiltrated with many lymphoid cells and a slight amount of hemorrhage.

The diagnosis was hemorrhagic mucocele of the appendix.

My interest in mucocele of the appendix was stimulated not only because of the rarity of this abnormality but also because it is a challenge to the diagnostic acumen of the general surgeon.

The frequency of the disease is of interest because, in reviewing the literature, I find that there have been approximately 250 cases reported since Virchow's[1] classic description of mucocele in 1863. Castle,[2] in a total of 13,158 autopsies, found twenty-eight cases, or a frequency of about 0.2 per cent. Mayo and Fauster[3] reviewed the surgical cases of the Mayo Clinic from 1917 to 1930 and found that mucocele of the appendix was encountered only seventy-six times in 31,200 cases in which appendectomy had been performed, a frequency of about 0.24 per cent.

A description of the pathologic changes occurring in the development of mucocele of the appendix is found in the work of Deaver,[4] and Vorhaus.[5]

The first process, according to Vorhaus, is assumed to be due to recurrent infections of the appendix causing a gradual stenosis of the lumen at one or more points distal to the obliterated lumen; sterile contents are presupposed. Then in the presence of actively secreting mucous glands a distention occurs, and theoretically there is a change in the mucus resulting in the transformation of mucin into pseudomucin.

The facts favoring this theory are as follows: There is a complete or almost complete stenosis of the lumen, or else with the increasing distention the fluid would be forced out. Secondly, there cannot be any pathogenic bacteria or else empyema or gangrene would result. Lastly, an active mucous membrane secreting mucus in excess of its absorption is necessary or distention would not occur. This results in the development of either rupture of the mucocele causing pseudomyxoma peritonaei or a thin walled watery cyst due to cessation of activity of the mucous glands which eventually becomes atrophic as a result of pressure atrophy. In my case the cystic fluid was hemorrhagic, probably owing to a ruptured blood vessel after the proximal portion of the appendix had become twisted.

Thus the rupture of a mucocele into the peritoneal cavity produces a condition of potential malignancy, pseudomyxoma peritonaei, the resulting effect on the patient and future response to treatment depending entirely on whether or not the mucous membrane lining the mucocele has been sufficiently destroyed by pressure atrophy.

The most common cause of pseudomyxoma peritonaei is due to pseudomucinous cystadenoma of the ovary. Therefore it is more frequent in the female, while mucocele of the appendix is the only known cause of pseudomyxoma peritonaei in the male.

The symptoms are vague and not characteristic of any specific clinical entity, especially the uncomplicated cases. Other than a history of (1) abdominal distress, (2) a palpable mass in the right lower quadrant of the abdomen, there are no other constant features. These points were the only constant factors mentioned by both Mayo and Fauster[3] and Dannreuther[6] in their reports. Although my patient had the symptoms of an acute surgical condition within the abdomen, which was due to a 120 degree rotation of the mucocele on the proximal portion of the appendix, these acute symptoms may be those of obstruction of the intestine, which has been reported to occur when the mucocele becomes invaginated into the cecum.

However, as a rule most of these patients tolerate these vague symptoms until they become so distressing and the pain so intensified that they voluntarily seek relief.

The diagnosis of mucocele of the appendix or pseudomyxoma peritonaei of appendical origin is usually made at autopsy, or at the operating table in a case with a preoperative diagnosis of ovarian tumor with or without a twisted pedicle, uterine fibroids, carcinoma of the cecum, terminal ileitis, intestinal obstruction or intraperitoneal neoplasm. In my case a diagnosis of ovarian tumor with twisted pedicle was made because of the acute onset of symptoms, the exquisite tenderness, the fever and the high leukocyte count. The disease is most common in middle aged and elderly women although my patient was only 16. There are no constant symptoms or signs which are pathognomonic of this disease. While roentgenographic evidence of mucocele of the appendix following a barium enema was used by Vorhaus,[5] Simon,[7] LeWald[8] and Lifvendahl and Ries[9] in the only preoperative diagnosis of mucocele of the appendix, this procedure does not always give constant results, since usually the lumen is stenosed or at best there may be an occasional mucocele with intermittent patency of the proximal end of the appendix.

However, with a history of vague gastrointestinal complaints and a palpable tumor mass in the right lower quadrant of the abdomen one should at least include mucocele of the appendix in the differential diagnostic considerations.

The treatment of mucocele of the appendix and pseudomyxoma peritonaei is definitely surgical. In the uncomplicated cases surgical removal is done with extreme caution to prevent rupture of the mucocele, while in complicated cases of mucocele of the appendix with pseudomyxoma peritonaei removal of the remaining parts of the ruptured mucocele and removal of as much of the mucoid gelatinous material and implants as possible are followed with roentgen therapy.

CONCLUSIONS

1. Mucocele of the vermiform appendix is a clinical rarity but is important because of its disastrous complications.
2. Its clinical incidence is approximately 0.24 per cent.
3. It is one of two known causes of pseudomyxoma peritonaei.
4. The clinical diagnosis is extremely difficult unless this condition is kept in mind, since there are no constant pathognomonic signs or symptoms especially incident to mucocele of the appendix.
5. The treatment is surgical.

SULFANILAMIDE IN THE TREATMENT OF SMALLPOX

WALTER O. MCCAMMON, M.D., SPRINGFIELD, KY.

I have recently treated seven cases of smallpox, four with sulfanilamide and three with symptomatic treatment:

CASE 1.—Mrs. G., aged 44, a housewife, white, first observed Jan 18, 1939, complained chiefly of severe backache and fever coming on rather suddenly during the preceding night. At first she felt chilly but did not have a definite rigor. This was accompanied with severe aching of the back in the lower lumbar region, across the hips and down the back of the legs. There was considerable headache and some nausea but no vomiting. There was some discomfort in the throat but no cough. There was no constipation, diarrhea or disturbance of the urinary system. There had been very little sweating. The patient was rather obese and appeared to be extremely ill. The skin was dry, the face was flushed and there was some restlessness. The temperature was 103.2 F.; the pulse rate 96 and the blood pressure 140 systolic, 90 diastolic. The eyes and nose were not congested but the throat showed red, cryptic, slightly enlarged tonsils and some redness of the pharynx. The chest was clear and there was no cardiac irregularity. There was no abdominal tenderness and no enlargement of the abdominal organs. The reflexes were normal. There was no rash on the skin. The urine showed a slight trace of albumin, with a high specific gravity but no pus cells, casts or erythrocytes.

The patient was given acetylsalicylic acid 5 grains (0.32 Gm.) every three hours; there was no question of her not staying in bed. The following day there was little change in the patient's condition other than a slight lowering of the temperature (101

F.). The acetylsalicylic acid seemed to ease the aching somewhat. On the third day the temperature was normal and the patient was feeling much better and was up about her household duties. On the fifth day the patient came to my office complaining of a "breaking out." She was covered—scalp, face, chest, arms, legs, palms and soles—with about 200 pustules about the size of a small pea, sitting on a red areolar base. On the palms and soles the pustules were very hard and tense. They contained a semipurulent material, which on smears showed short chained streptococci. On the seventh day definite umbilication was seen; on the ninth the pustules were beginning to dry, and on the thirteenth they were desquamating. The eruption was accompanied by a slight elevation of temperature (from 99 to 100.6 F.) and mild prostration.

CASE 2.—H. G., aged 18, the son of patient 1, a farmer, first seen February 5, complained chiefly of severe backache and headache, some nausea but no vomiting. The onset had been rather sudden the night before when a rather severe chill was experienced while he was attending a movie. There was no cough, constipation or symptom referable to the urinary tract. The symptoms followed the identical pattern of those presented by his mother. The patient was well developed and well nourished. The skin was dry and clear. The temperature was 104 F., the pulse rate 110 and the blood pressure 118/80. Otherwise the examination was negative. He was given acetylsalicylic acid 5 grains every three or four hours and sulfanilamide 10 grains (0.65 Gm.) every three hours. The following day the patient's condition was unchanged except for very slight cyanosis of the lips and some duskiness of the skin. There was no rash. On the third day the temperature was 99 F. and the patient felt much better. The aching had abated but there was some nausea. The dosage of sulfanilamide was reduced to 5 grains every four hours. On the fourth day the temperature was 98.2 F. and the patient was much improved. There were three very small dark red macules on the right forearm and three or four in the scalp. These were rather tender and caused some itching. On the sixth day the patient was out of bed and the following day he was attending to his farm work. The macules disappeared on the sixth day and there was no further eruption.

CASE 3.—Mr. F. G., aged 53, the husband of patient 1, a farmer, first seen February 8, complained chiefly of severe headache across the forehead; there was also some backache and generalized aching in the limbs. There were no other complaints. The temperature was 102 F., the pulse rate 96 and the blood pressure 138/96. The examination was otherwise negative. He was given acetylsalicylic acid 5 grains with phenobarbital one-half grain (0.032 Gm.), but this gave no relief and dilaudid 1/32 grain (0.002 Gm.) was given at intervals of about ten hours to relieve the aching. Marked restlessness and semidelirium also developed. On the third day the temperature, which had varied between 101 and 103 F., fell to 99 F., and the next day there was a widespread eruption of discrete red macules and papules about the size of a pea, the temperature became elevated again to 101 F., and the papules and macules in two days were well marked pustules, which soon became umbilicated. On the eleventh day of the disease they began drying up and on the fifteenth day they were practically all gone. The patient had been vaccinated forty years before. None of the other patients in this series had been vaccinated.

CASE 4.—Mrs. S., aged 30, daughter and neighbor of patient 1, a housewife, had been in and out of her mother's house while her mother was ill and became ill February 6 with symptoms very similar to those described in the foregoing cases, namely backache, headache, fever and some nausea. I first saw her February 7. The temperature ranged from 102 to 104 F. for three days and on the fourth day returned to normal. During this period she received sulfanilamide 10 grains every three hours and acetylsalicylic acid 5 grains as needed. On the fourth day a few small macules were noted on the wrists and forehead. The medication was discontinued on the fifth day, the macules disappeared on the sixth and she was about her household duties on the seventh.

CASE 5.—Mr. C., aged 34, a son-in-law of patient 1, a farmer, when first seen, February 8, had been ill for two days, complaining of intense backache, headache and high fever. The patient was well developed and well nourished and was apparently very ill. The temperature was 104 F. Acetylsalicylic acid 5 grains with phenobarbital one-half grain gave some symptomatic relief. On the fourth day the temperature was normal and no eruption was noted. On the fifth day, however, many macules were noted over the body which rapidly became papular, then vesicular and pustular, followed by umbilication on the ninth day of the disease and drying up and crusting on the fifteenth. The eruption, as in the other cases described, covered the entire body including the palms and soles, and there were some papules in the pharynx and nose.

CASE 6.—Mrs. C., aged 30, a daughter of patient 1, a housewife, was first seen February 18 after being ill about thirty-six hours. She had had a rather sudden onset, had complained of intense backache and headache and had vomited twice. The history and symptoms were identical with those in the preceding cases. Her temperature was 103 F. She was given sulfanilamide 5 grains every three hours and acetylsalicylic acid as needed for the aching. On the fourth day the fever subsided and on the sixth there were three well defined vesicles on the right cheek which went through the typical evolution of pustulation, umbilication and desquamation. During the last phase of the disease there was some slight elevation of temperature (from 99 to 100 F.). On the tenth day of illness she was out of bed and feeling fairly well.

CASE 7.—Mr. W., aged 30, white, a farmer, first seen February 23, had spent the night with patient 3 on February 15. During the night of February 22 he rapidly became very ill; he had a light chill that lasted fifteen minutes and aching of the back and limbs, and he vomited. When he was seen he was very restless. The temperature was 104.2 F. The pulse was 110. There were no significant changes found on examination other than the fever and the restlessness. Morphine one-fourth grain (0.016 Gm.) was required to relieve the backache. He was given sulfanilamide 10 grains every three hours. On the fourth day the temperature was normal and he was feeling very well. A few macules developed on the forearms which lasted about twenty-four hours. He was back at work on the seventh day.

COMMENT

These seven cases are all identical as to onset and the initial period, typical of smallpox. All show a sudden onset of severe and excruciating backache and headache with an abrupt rise in temperature persisting for three days. There seemed to be very little variation in the patients who received sulfanilamide and those who did not. However, in the patients who received sulfanilamide there was no pustular eruption except in case 6, in which three pustules occurred. In the cases in which sulfanilamide was not used there was the typical eruption of smallpox. Sulfanilamide seemed to abort the second phase of smallpox with its pustulation and scarring; there were some macular spots on all those receiving sulfanilamide, but they were evanescent. As far as morbidity goes, the patients who received sulfanilamide recovered immediately after the subsidence of fever and the symptoms of the initial phase. The effect of sulfanilamide in patients with the typical eruption already present is not known, since the patients who received sulfanilamide were started on the treatment before an eruption appeared.

The occurrence of these seven cases in the same community and mostly in the same family during an outbreak of smallpox, and the absence of an eruption in those who received sulfanilamide therapy does not seem to be coincidental.

SUMMARY

1. Three of the seven patients with smallpox were treated symptomatically and in all three the typical eruption of smallpox developed.

2. The remaining four patients were given sulfanilamide, and in three there was only an evanescent macular eruption which rapidly disappeared; in the remaining case there were only three pustules.

3. The patients who were given sulfanilamide were back at work about a week sooner than those who did not receive it.

4. Sulfanilamide seems to have a beneficial effect in the treatment of smallpox when administered early in the disease.

INTERSEXUALITY

ROBERT C. MOEHLIG, M.D., AND NORMAN M. ALLEN, M.D.
DETROIT

Intersexuality is an interesting phenomenon and cases of this type are not frequently encountered. In his book on genital abnormalities Young [1] has given a complete review of the subject and has presented cases of his own.

REPORT OF CASE

The following case is of interest:

E. Z., a student aged 12 years, was seen Sept. 26, 1932, by the late Dr. Max Ballin, having been referred by the Childrens' Center of Detroit because of abnormal sexual development.

At the time of the birth of the patient, the mother was told that there was some abnormality of the sex organs but that the baby's sex was female. The child was christened Ida and was reared as a girl. At the age of 10 a school nurse discovered that there was some abnormality of the sex organs but did not report the condition until the child was ready to enter high school at the age of 12. There had been no menstruation, either normal or vicarious. There was nothing significant in the past history.

The father is Polish and the mother is Lithuanian; both are living and are of average build.

The patient was well built and well nourished, of stocky type, with a height of 61½ inches (156 cm.), weighing 116 pounds (52.6 Kg.), with dark complexion and dark brown hair (fig. 1). The patient had a deep voice like a young man of 16 or 17. There was some hair on the upper lip. The breasts were of the flat male type. There was a female type of distribution of pubic hair. The penis was somewhat smaller than normal, hook shaped with chordee Hypospadias of the scrotum, urethra and prepuce was present. The scrotal halves were fairly well developed and split in the middle and did not contain testicles (fig. 2).

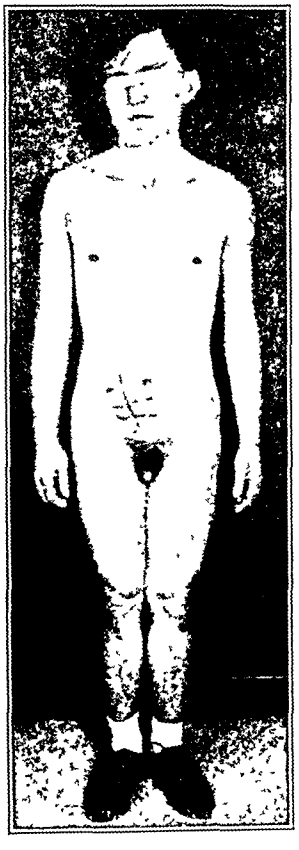

Fig. 1.—Appearance of patient June 15, 1938. Note the short, stocky build with female distribution of pubic hair

There was a rudimentary vagina 6 cm. in length and about 1 cm. below the penis (fig. 3). A well developed prostate could be felt by rectal examination. Physical examination was otherwise negative.

Laboratory examination revealed that the blood, urine and chemistry of the blood were normal; the Wassermann reaction was negative. The blood pressure was 110 systolic, 72 diastolic. The basal metabolism was plus 10 per cent.

X-ray examination of the skull was essentially negative; that of the chest and urinary tract was also negative. There was no suggestion of an adrenal tumor.

It was decided that the patient was of the male sex and he was therefore rechristened Eugene, he was sent away for two weeks, his hair was cut so that it conformed to the masculine type and he donned long trousers.

Beginning Dec. 22, 1932, Dr. Ballin performed a series of corrective plastic operations. In the first stage the chordee was corrected; a constricting band between the corpora cavernosa was excised which permitted straightening of the penis. Jan. 17, 1933, a plastic operation on the glandular part of the urethra was performed, and June 24 the fistula which had formed posterior to the glans was operated on. June 5, 1934, an anterior urethra was constructed from the skin flaps of the posterior aspect of the penis. This urethra was constructed over a rubber catheter but was not connected to the original orifice of the bladder. Sounds were passed at periodic intervals every two or three weeks up to the present. His condition has been very satisfactory with this series of operations except for the fact that cystitis has persisted.

Fig. 2.—Showing scrotal halves with vaginal opening

April 27, 1938, an acute appendicitis developed and on April 28 an acutely inflamed appendix was removed by one of us (Dr. Allen). The remainder of the abdomen was carefully examined and a small uterus was found with bilateral tubes and normally developed ovaries with the fimbriated ends of the tubes found patent. No rudimentary testicles were found. He made an uneventful recovery.

Gonadotropic assay of the urine was attempted several times but, because of bacterial infection present in the urine, all animals used in the tests died.

As he had reached the age of 18, a discussion with the patient concerning his psychosexual aspect was undertaken. He stated that he has always liked girls and for the last two years has had erections. He has had frequent orgasms with emissions, the discharge coming through the perineal urethra. Several specimens of this discharge were collected but no spermatozoa were found, nor were there any spermatozoa in the urine collected immediately after the discharge. He masturbated quite frequently and became sexually excited very easily. He expressed a desire to marry in the future but felt embarrassed because he had to sit down to urinate. This was his only complaint. He shaved once a week, for there was but a sparse growth of hair present on his face, being more like the "down of youth."

He was rather quiet in his speech, the voice being deeply masculine. He was of a retiring nature and it was difficult to have him discuss his case freely; he cooperated well in the examinations.

COMMENT

This patient would fall in the group termed by Klebs [2] as pseudohermaphroditismus masculinus internus. In this group, in addition to male sex organs, tubes, uterus and vagina have

From the Department of Medicine, Harper Hospital and Wayne University, and the Department of Surgery, Harper Hospital.

1. Young, Hugh: Genital Abnormalities, Hermaphroditism and Related Adrenal Diseases, Baltimore, Williams & Wilkins Company, 1937.

2. Klebs, cited by Young.[1]

also developed. According to Creevy,[3] one can classify any pseudohermaphrodite by the use of two adjectives: The first (masculine or feminine) indicates the nature of the sex gland. The second (external or internal, complete) indicates whether it is the sex of the internal or of the external or of both groups of genitalia that differs from that of the gonad.

Rubovits and Saphir,[4] in reporting their case of intersexuality, say: "Our microscopic evidence of testicular tubular atrophy and absence of spermatogenesis is enough to rule out the diagnosis of true hermaphroditism and to confirm again the fact that true hermaphroditism never has been found in man." Young,[1] on the other hand, states that his is the ninth accepted case of hermaphroditismus verus on record.

Psychically the patient considered himself as belonging to the male sex and was fond of the females. He says that he "feels mixed up" because he was reared as a girl and was "changed over." He has desires for intercourse with females, has erections and a discharge no doubt prostatic in origin, since no spermatozoa were ever found in the discharge or in the urine passed immediately after the discharge. No trace of a testicle could be found at operation.

His build is distinctly masculine, as shown in figure 1. His voice is deeply masculine and was present at the age of 12, indicating a well developed cartilaginous larynx. He is only 63 inches (160 cm.) in height, showing that the union and

Fig 3.—Forceps in vaginal opening.

ossification of the epiphyses took place prematurely. His appearance is very much like that seen in achondroplastic dwarfs with short muscular arms and legs.

SUMMARY

The case of intersexuality here reported is classified according to the Klebs grouping as pseudohermaphroditismus masculinus internus. In this group the male individual has also tubes, a uterus and a vagina. Our patient had, in addition, well developed ovaries. No testicles were seen or palpated.

The prostate was well developed. The patient had been reared as a girl until the age of 12 years, when he was rechristened with a masculine name and has since lived as a male. His sexual inclination is toward the female sex. He has erections and orgasms with a prostatic discharge through a perineal urethra. Micturition can be accomplished only in the sitting position.

964 Fisher Building.

DEATH FROM GRANULOCYTOPENIA AFTER SULFANILAMIDE THERAPY

PHILIP CORR, M.D., AND RALPH N. ROOT, M.D., RIVERSIDE, CALIF.

Sulfanilamide is such a valuable drug that it is being used very widely and with perhaps some lack of caution. For this reason it seems wise to report another fatal case to the small series of severe granulocytopenias resulting presumably from its use.

REPORT OF CASE

Mrs. M. S., white, American, aged 22, entered the Riverside County Hospital Sept. 19, 1938, because of a severe throat infection of about two weeks' duration. There had been a high fever with vomiting for two days. At the time of entrance into the hospital there was no other relevant history.

On physical examination at that time the patient was well developed and well nourished and appeared acutely ill. The temperature was 104.6 F., the pulse 136 and the respiratory rate 28. A general physical examination was done, examination of the vagina and rectum being omitted; the following observations were made: There were several superficial ulcerated areas about the lips. A few white patches were noted on the gums. The breath was foul. The tonsils were moderately enlarged and covered with a grayish, necrotic membrane. No bleeding was noted on traumatization of the membrane. The pharynx was injected. There was a mild anterior cervical adenitis bilaterally. On the posterior surface of the left hand between the first and second fingers was a small linear abrasion, surrounded by a small area of inflammation.

A smear from the throat revealed many diphtheria-like organisms. On the basis of this report 65,000 units of diphtheria antitoxin was given promptly. The following day culture of material from the throat was negative for diphtheria and the smear was reported negative for diphtheria. Numerous fusiform bacilli with a few spirilla were noted.

On the day of entrance the laboratory reported the hemoglobin content to be 68 per cent, with 3,120,000 red blood cells, 800 white blood cells with 8 per cent polymorphonuclear neutrophils, 2 per cent eosinophils and 90 per cent lymphocytes. The condition was then recognized as agranulocytic angina. Pentnucleotide was given intramuscularly in four doses of 10 cc. between meals on September 20 and 21. A transfusion of 550 cc. of whole citrated blood was given September 21.

September 20, the day after admission to the hospital, the white blood cell count improved to 1,100 per cubic centimeter with 48 per cent lymphocytes and 52 per cent polymorphonuclear neutrophils. The following day, the day of the patient's death, the white blood cell count was 2,000 with 56 per cent lymphocytes and 44 per cent neutrophils.

The patient's temperature remained around 103.6 to 105 F. until two days after her entrance into the hospital, when it gradually rose to 107.8 (rectal) before death. She was delirious much of the time the last day. At the time of death the small inflammatory lesion of the left hand amounted to a cellulitis involving most of the left hand posteriorly.

After repeated questioning by both of us the patient finally admitted, on the day of her death, that she had taken some tablets for leukorrhea. After this admission it was found that on Aug. 27, 1938, she had taken 80 grains (5 Gm.) of sulfanilamide, repeating this dose the following day. She then took 40 grains (2.6 Gm.) a day for six days and then 20 grains (1.3 Gm.) a day for seven days, the last tablets being taken September 11, eight days before she entered the hospital. Altogether 540 grains (35 Gm.) was given in a period of fifteen days by an osteopathic physician. No check was made of the blood count until entrance into the hospital, and no mention

was made by this practitioner of the medicine given when he sent the patient to the county hospital as probably having diphtheria.

The Kahn test was strongly positive, the report being made the day after the patient's death. A blood culture was negative after ten days' incubation. The urinalysis on entrance revealed a heavy trace of albumin, with a negative sugar reaction, from 6 to 8 white blood cells per high power field, and a markedly positive acetone reaction.

Autopsy was done by one of us (R. R.) on the embalmed body sixteen hours after death. There was a soft, nonpitting swelling of the dorsum of the left hand. There was an abrasion between the first and second fingers of the left hand with considerable dark bluish discoloration in that region. There was moderate swelling of the neck with palpable lymph nodes bilaterally. No other lymphadenopathy was noted.

When the pleural cavity was opened no free fluid was encountered, and no adhesions were noted. The pleurae showed evidence of some inflammation. There were several dark purplish hemorrhagic areas seen on the surface of the lungs, most marked in the right upper lobe. These were from 1 to 5 cm. in diameter and on cut section appeared dry, rough and raised. They were not limited to the surface and were not wedge shaped. There was some evidence of necrosis present in the centers. Otherwise the lungs were essentially normal. The pericardium was markedly injected and there were several small hemorrhagic areas. No abnormal amount of fluid was seen in the pericardial sac. The heart was not enlarged. The heart muscle was firm and of good tone, while its chambers, valves and vessels showed no abnormalities.

No free fluid was found in the abdominal cavity. The peritoneum was white and glistening. No adhesions were present. The liver appeared congested and there was a small dark area noted on the anterior surface of the right lobe which was soft and necrotic on cut section, but no free pus was present. The spleen was soft and moderately enlarged and had a smooth capsule. There was no evidence of abscess or of infarction. The stomach was dilated but essentially normal. The small and large intestine showed no abnormalities. The kidneys were moderately enlarged. Thin capsules stripped with ease, revealing congested surfaces. The parenchyma was poorly outlined. There was no dilatation of the ureters. No inflammation of the bladder was noted. The tubes and surrounding tissues were markedly congested and thickened, but no exudate was present. The ovaries were essentially normal. The uterus was small.

Sections of tissue from various organs were removed and examined by Dr. Oran I. Cutler of Loma Linda. His report showed the following:

Microscopic Examination.—The wall of the fallopian tube was congested but there was practically no scarring and no leukocytic infiltration was present. There was edema of the lung, and fairly numerous heart disease cells were present. In one section there were many masses of bacteria but no leukocytic reaction. In the ovaries there were some cysts lined with tiny dark cells. The kidney showed no definite pathologic changes. The pulp of the spleen was loose and relatively acellular. The liver showed some cloudy swelling.

The final diagnosis was agranulocytic angina caused presumably by sulfanilamide.

There was serologic evidence of syphilis.

COMMENT

Nine deaths have previously been recorded in the literature from agranulocytosis apparently caused by sulfanilamide according to a compilation by Kracke [1] in October 1938. A few more cases have been recorded in which recovery has taken place. Many more have probably occurred—some unrecognized, some unreported. With the increasing use of this valuable drug, more cases may be expected.

It is assumed that the drug, added to some unknown factor, produces a maturation arrest of the granulopoietic tissues.

There should be some simple means of avoiding this grave complication. One suggestion is commonly made [2] to have repeated frequent blood counts. This is an excellent suggestion and should be given serious consideration. However, if followed rigidly and as a routine by all those giving sulfanilamide it would probably cost many more lives by restriction of the use of sulfanilamide than it would save by prevention of agranulocytic deaths, which are apparently very rare. In the case of agranulocytosis from aminopyrine, it is relatively easy to solve the problem by substituting some other similar drug. As yet we have not found a comparatively effective, relatively harmless substitute for sulfanilamide.

Even with frequent blood counts it has not been proved that this will prevent deaths from agranulocytosis. In Young's [3] case examination of the blood five days before death failed to reveal an impending granulocytopenia, although the white blood count was reduced from 12,000 to 7,800. The granulocytopenia developed in this case four days after the sulfanilamide was discontinued.

A second suggestion has been made which should receive serious consideration, i. e. that any patient having toxic symptoms of any nature should (1) be denied further use of the drug or (2) should be watched very closely. This would seem to be an excellent rule to follow. Further use of the drug should be denied if the condition being treated is not of major seriousness, and the policy of strict observation should be enforced with blood counts every other day if sulfanilamide therapy is urgent.

A third point in preventing agranulocytic complications might be made concerning the dosage. In an adult the smallest dose of sulfanilamide given preceding the onset of agranulocytosis was 25 Gm., and in that case it was probable that the patient had taken more. In practically all the other cases reported 35 Gm. or more had been ingested in a period of two weeks or more. With our present information we might say that the general practitioner might safely give up to 20 Gm. of sulfanilamide before being concerned about agranulocytosis. That dosage may well care for many of the simpler infections treated with this drug.

This case further substantiates the causal relationship between sulfanilamide therapy and agranulocytosis.

NICOTINE POISONING WITH A SALT OF NICOTINE

A. F. WAGNER, M.D., AND MILES E. DRAKE, PH.D.
LOS ANGELES

The reported instances of fatal nicotine poisoning according to Webster [1] and to Beeman and Hunter [2] are relatively infrequent. The nicotine insecticides are the usual preparations of nicotine used for suicidal purposes. To our knowledge there have been no reports of poisoning with a dry salt of nicotine.

The case reported here was one of suicide which came to the Los Angeles County coroner. The autopsy revealed no evident cause of death. The viscera were therefore sent to the county chemist for analysis.

Following the usual routine for extracting alkaloids there was left, after evaporation of the alkaline ether extract of the stomach contents, a considerable quantity of white crystalline material. This white residue was purified and proved to be nicotine by the mercury bichloride and gold chloride microchemical tests and this was confirmed by biologic tests on frogs. Chemical examination showed that the nicotine salt was not the sulfate or hydrochloride but the tartrate. Later crystals of nicotine tartrate were identified in some cigarets found among the effects of the deceased. As the patient was a pharmaceutical chemist and had access to the salts of nicotine, one may readily understand how such a little used salt of nicotine was employed in this instance.

Dr. Wagner is autopsy surgeon, Los Angeles County; Dr. Drake is assistant to the county chemist.

Special Article

TYPHOID IN THE LARGE CITIES OF THE UNITED STATES IN 1938

TWENTY-SEVENTH ANNUAL REPORT

The means employed for obtaining data for this report were described last year. A communication was addressed to the health officer of each of the ninety-three cities, requesting the number of deaths from typhoid both among residents and among nonresidents which were recorded for 1938. The difficulty of obtaining an adequate estimate of population continues and will harass the public health official until the 1940 census has been completed. In all instances the local estimate when furnished by the health officer has been used. There are some who feel that their cities have grown slightly during the past years and others take credit for a decrease in population. Study indicates that in no instance is a grave statistical error committed by using the local estimate rather than falling back on the 1930 census figures. It is hoped that after the 1940 figures become available these tables can be revised, but even then it is anticipated that the corrections will be of only a minor character.

Paratyphoid has again been excluded. In tables 1 to 8 inclusive (as well as in table 10) a special note has been made of cities in which all deaths occur among nonresidents. Similar notation has been added for the death rates for 1936 and 1937 but in no instance for preceding years. Another symbol has been used to indicate those cities in which more than one third of the reported deaths were stated to have been among nonresidents.

Special attention is called to the cities listed in table 9 which report no typhoid death during the past two years. Bridgeport reports no death in five years, Fort Wayne no death in four years, South Bend and Utica no death in three years. Attention is also directed to the seven cities (Toledo, Hartford, Syracuse, Worcester, Springfield, Evansville and Camden) which are placed among those of first rank rather than on the honor roll in table 10 merely because they have been charged with deaths among nonresidents. It is quite appropriate to think of these cities as belonging in the honor group. Local circumstances beyond the control of the public health officer frequently require the hospitalization in large cities of cases which belong in the surrounding rural communities. This same comment applies to those cities in which a relatively high share of the typhoid deaths occurred among nonresidents.

Seven of the large New England cities report no death from typhoid in 1938 (table 1). Only four of these cities (Bridgeport, Fall River, Lynn, New Bedford) were in this same honor group in 1937. Bridgeport has extended its good record to five years. Somerville, which last year recorded no death for four years in succession, reports one death among residents in 1938. Springfield, after passing through a period of three successive years with no death among residents, reports one death among nonresidents in 1938. Providence reports no death in 1938 among twelve resident patients. Three of these cases occurred in one family and are attributed to the fact that children were playing near an old privy. Of two deaths reported from New Haven, one occurred in a nonresident. Of five deaths reported from Boston, three were among nonresidents. Hartford, with but one death and that in a nonresident, reports that in 1936, during the Connecticut River flood, 97,334 typhoid inoculations were given and that during the 1938 flood 4,435 such protective treatments were administered to Hartford residents. The New England cities as a whole (population 2,645,438), although reporting a rate as low as that for 1937, have lost first place among the grouped cities (table 13).

‡ Rate computed from 1930 census population, as no local estimate was given
‖ Corrected rate. In review for 1936, Yonkers reported cases instead of deaths

The lowest rate, of 0.35, is reported from the East North Central states, while second place goes to the West North Central cities and third place to the Middle Atlantic cities. In the New England cities there were recorded twelve deaths in 1938, a number identical with that of 1937.

The Middle Atlantic states have a group rate (0.44) which is significantly lower than that of 1937 (0.51). The 1938 rate is slightly below that of the New England

13,469,996) there were fifty-nine deaths in 1938 compared with sixty-eight in the preceding year. There are two geographic areas which have a lower death rate for 1938, the East North Central and the West North Central.

The rate for the South Atlantic cities (*1.74*) is much improved over that of 1937 (1.96) but is not as low as that of 1936 (1.55). In these cities (population 2,638,626) there occurred forty-six deaths in 1938 and fifty-one in 1937. There was no city without a death in 1938, although six of the nine cities in this group report that one third or more of the deaths occurred among nonresidents. Baltimore reports thirteen deaths, eight among residents. It is reported that, in investigating sources of infection in typhoid cases, there were located sixteen carriers presumably responsible for twenty cases. Many cities in the South continue to be embarrassed by the high percentage of deaths among nonresidents. The large cities serve as hospital centers for the neighboring suburban and rural areas which are without adequate means of caring for the communicable diseases and which frequently suffer from the want of whole-time local public health supervision Of five deaths recorded for Richmond, four were

among nonresidents; of six in Washington, two were among nonresidents Three deaths among nonresidents are included among the five deaths reported for Miami It is stated that for one nonresident death the infection was contracted prior to the arrival of the patient in Florida. Miami originally reported eight deaths for the year 1937. The director of health states that this should now be changed to six deaths for that year Of eight deaths recorded by Jacksonville, but one occurred in a nonresident. The health department reports that a plan is being developed to require inoculation of all food handlers against typhoid. This city continues to serve as a medical center for seven or eight nearby rural counties with no public health units. Such a unit has, however, recently been established in Duval County, which includes the territory immediately surrounding Jacksonville. After two consecutive years with no typhoid death, Tampa records one death among residents for two reported in 1938.

The East North Central cities (population 9,907,440) can boast of the best record for 1938 (rate 0.35). In 1937 there were sixty-one deaths reported from these

cities. In 1938 the number of deaths had dropped to thirty-five. There are seven cities which report no death and two additional cities (Toledo, Evansville) which record no death among residents. In addition to this there are three cities (Detroit, Cleveland, Dayton) in which one third or more of the reported cases were stated to be in nonresidents. Fort Wayne reports no typhoid death in four years, South Bend no death in three years, Milwaukee and Canton no death in two years. There has been no death among residents in Grand Rapids and Peoria during the past four years. Toledo reports no resident death in two years. Dayton records a significantly high proportion of deaths among nonresidents during each of the past three years. Of three deaths each in Cleveland and Detroit, one in each

Incomplete data.

city was of a nonresident. Chicago reports a total of twelve deaths, two of which were stated to be in nonresidents.

The six cities in the East South Central Group show an increase in the death rate (2.10 in 1937, 2.36 in 1938). This rate, however, is considerably below that of 1936 (3.35) and that of the quinquennial period 1931-1935 (4.81). The actual number of deaths in these six cities increased from twenty-eight in 1937 to thirty-two in 1938. No city in this group is without a death in 1938. The influence of the surrounding rural areas in contributing to the hospital load and thus to the death rate of the urban centers in the South is well illustrated by the fact that in Birmingham, Memphis and Nashville more than one third of the deaths were among nonresidents. Birmingham, with five deaths, reports two in nonresidents; Memphis, with nine deaths, records four in nonresidents; Nashville, with eight deaths, reports three in nonresidents. Chattanooga reports two deaths among residents, with a comment that in both instances the source of infection was outside the city. Special mention of the influence of the surrounding rural area and the Negro population to the death rate for Memphis was made in our report a year ago.

TABLE 9.—*Thirteen Cities with No Typhoid Death in 1937 and 1938*

Bridgeport*	Lynn	South Bend†
Canton	Milwaukee	Tacoma

Fort Wayne**	Reading	Wichita
	Seattle	

* No typhoid death in five years.
** No typhoid death in four years.
† No typhoid death in three years.

The West North Central group (population 2,785,688) reports a noteworthy reduction in the death rate (0.76 in 1937, 0.40 in 1938). There is but one group of cities (East North Central) which has a lower death rate. Four cities (Wichita, Minneapolis, Kansas City, Kan., Omaha) report no typhoid death in 1938 and the first three of these record no death among residents in 1937. Minneapolis has had no death in a resident during the past three years. Duluth, after two years with no death, now reports a single death in a resident. This death, however, is sufficient to move Duluth from the head to the bottom of the table. This is the only group in which there is no city with a death rate in

* All typhoid deaths were stated to be in nonresidents.
† One third or more of the reported typhoid deaths were stated to be in nonresidents.

excess of 1.0. Not only do these cities as a group have a low death rate but actually the lowest number of deaths. There were eleven deaths in 1938, compared with twenty-one in 1937. The Iowa State Health Department reports that no statistical correction is as yet available regarding deaths among nonresidents and consequently such information is not included in the

report for Des Moines. It is likely, however, that this same error might creep into the statistics of many other cities widely scattered throughout the United States.

The eight cities of the West South Central group did not fare so well. Here the rate increased from

1938	36,972,985	248	0.67##

* The following fifteen cities are omitted from this table because data for the full period are not available: Canton, Chattanooga, Dallas, Fort Wayne, Jacksonville, Knoxville, Long Beach, Miami, Oklahoma City, South Bend, Tampa, Tulsa, Utica, Wichita, Wilmington.

† Data for Fort Worth lacking.

‡ The rate for ninety-three cities in 1935 was 1.03 (total population 87,437,812, typhoid deaths 385), whereas in 1930 it was 1.64, and in 1933 and 1934 it was 1.24 and 1.25, respectively. The 1931-1935 average for the ninety-three cities is 1.31.

§ Rate for ninety-three cities in 1936 was 0.96 (total population 38,249,694, typhoid deaths 365).

Rate for ninety-three cities in 1937 was 0.82 (total population 38,885,435, typhoid deaths 318).

Rate for ninety-three cities in 1938 was 0.74 (total population 39,147,556, typhoid deaths 291).

Special Note.—Deaths for 1936 have been corrected, as Yonkers originally reported seven deaths and later corrected report to one death.

death rate. El Paso, with no death in 1937, reports a rate of 5.9 (six deaths) in 1938. All but one of these deaths are among residents. Oklahoma City records no data concerning deaths among nonresidents. Of six deaths in San Antonio, four were among residents; of eleven in Houston, nine were among residents; of twenty-nine in New Orleans, fourteen were among residents. With no death in a resident in 1936 and 1937, Dallas reports thirteen deaths for 1938, of which nine were among nonresidents.

The cities in the Mountain and Pacific states show a continued reduction in the rate (0.52 in 1938, 0.68 in 1937). There were recorded twenty-two deaths in 1938, twenty-eight deaths in 1937. In 1938 there were five cities with no death (Seattle, Tacoma, Portland, Salt Lake City, San Diego). Three additional cities (Oakland, Los Angeles, Spokane) record one third or more deaths which were in nonresidents. There was but one city with a rate in excess of 2.0 (Spokane). There were but three deaths in Spokane, two of which were among nonresidents. Two cities (Seattle, Tacoma) report no typhoid death in 1937 and 1938. Of five deaths in San Francisco, four were among residents. Of eight deaths in Los Angeles, five were among residents. Denver does not keep a record of deaths among nonresidents.

THE HONOR ROLL

The number of cities with no death from typhoid has increased to twenty-nine. In 1936 there were but eighteen such cities, in 1937 twenty-seven. Of particular significance are the data in table 9, which furnishes

TABLE 13.—*Total Typhoid Death Rate per Hundred Thousand of Population for Ninety-Three Cities According to Geographic Divisions*

	Population	Typhoid Deaths		Typhoid Death Rates				
		1938	1937	1938	1937	1931-1935	1926-1930	1921-1925

‡ Lacks data for Oklahoma City in 1936.

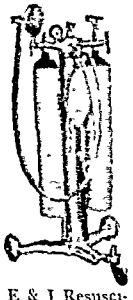
§ Lacks data for Oklahoma City.

the names of thirteen cities with no typhoid death in 1937 and 1938. Bridgeport and Fort Wayne have continued their excellent records. While last year there was but one city in the third rank (*Miami*), and this city would not have been included in this rank had the correct number of deaths been recorded, in 1938 we find three cities in this group, only one of which reports a significant number of deaths among nonresidents. As already stated, several of the cities in the first rank would appear in the honor roll were they not charged with deaths in nonresidents. Table 11 continues to show a swing "to the right," although the number of cities in the group having death rates from 50 to 99 has increased from one to three.

NEW LOW RECORDS ATTAINED

For the seventy-eight cities (table 12) for which complete data are available since 1910, there occurred 248 deaths from typhoid in 1938, which is the lowest of record (280 in 1937, 336 in 1936). The rate for this group of cities is for the fourth consecutive year less than 1.0. The rate for the ninety-three cities studied in 1938 is also below 1.0 (0.74) and below the corresponding rate for 1937 (0.82). This annual review again showed a downward trend in the death rate from

typhoid in the large cities of the United States. No outbreak of epidemic proportion has been recorded in these cities. Routine vaccination of the population is not practiced except under flood conditions. However, in progressive communities vaccination is urged for contacts to cases and for persons who travel widely in countries where sanitary conditions are not of the best. There seems to be a trend in some places to encourage the inoculation of foodhandlers, especially in the Southern states. The noteworthy gains for 1938 have been made in the East North Central and West North Central cities. The New England and Middle Atlantic groups have, on the whole, maintained their excellent rates of many years' standing.



Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

E & J RESUSCITATOR AND INHALATOR ACCEPTABLE

Manufacturer: E & J Manufacturing Company, 139 South Verdugo Road, Glendale, Calif.

The E & J Resuscitator and Inhalator may be used for producing artificial respiration by mechanical means or simply as an inhalator for providing a concentration of oxygen or a mixture of oxygen and carbon dioxide around the mouth and nostrils. The apparatus is available in three models, one portable and two for hospital service. The portable unit weighs 100 pounds complete with gas cylinders. The resuscitator side[1] of the appliance produces artificial respiration by setting up in the lungs a sequence of alternating positive and negative pressures. The stroke automatically adjusts itself within limits to the lung capacity of the patient. While both positive and negative pressures are set at the factory, the gas flow may be regulated by a control valve at the will of the operator. Since the gas volume is adjusted to the lung capacity of the adult to produce the proper number of respirations per minute, the same flow would cause a more rapid respiratory rate in a child with smaller lung capacity. A regulator control valve is placed on the apparatus, which enables the operator to reduce gradually the flow of oxygen, thus automatically reducing the number of respirations per minute.

E & J Resuscitator and Inhalator.

The inhalator side[2] of the apparatus supplies a constant flow of oxygen or oxygen and carbon dioxide mixture to the mouth and nostrils. The transfer from the resuscitator to the inhalator side of the device is accomplished by means of a lever, so that either one or the other technic is independently available.

The E & J Resuscitator and Inhalator is designed to be used in emergencies in which natural respiration has failed with resulting asphyxia. The portable unit may be employed by fire and police departments, by life guards and mine rescue squads, and by other trained organizations rendering first aid. The hospital unit is provided for such respiratory emergencies as arise in hospital practice.

When used as a resuscitator, gas pressure in the tank operates the pistons contained within the mechanism. A face mask is fitted tightly over the patient's nose and mouth after an "Airway" (a wire device for holding down the tongue to clear a passage to the trachea) is placed in the patient's mouth. Gas, after passing through and actuating the apparatus, enters the face mask through a hose and is carried into the trachea and lungs at a pressure of from 12 to 14 mm. of mercury. There is a safety valve on the mask which is set at the factory and releases at approximately 18 mm. of mercury. The gas is withdrawn under a smaller negative pressure of from 7 to 9 mm. of mercury below the atmospheric level. The exhaled gas returns through another hose to a separate cylinder, creating the vacuum in the mechanism, and is finally discharged into the atmosphere. Briefly, therefore, the resuscitator is operated by the energy of the gas stored in the tank under pressure, while the selfsame gas is used in the lungs for resuscitation purposes. If the throat is filled with mucus, an aspirator, a separate accessory, is available which utilizes the negative pressure phase of the resuscitator cycle to clear the air passages.

After natural breathing has resumed, by the turn of a lever the respirator is turned off and the inhalator turned on for such time as is deemed necessary. When the inhalator side is used, the gas passes from the tank through a regulating valve, thence into a rubber breathing bag and finally to the patient's mask. On exhalation, it passes through the auxiliary exhalation valve and out to the atmosphere. The inhalator side of the apparatus is similar in operation to other inhalators accepted by the Council.

In cleaning the apparatus, the firm recommends the use of 20 per cent aqueous solution of green soap, worked into a good lather, and the face cushion, celluloid mask, mask valve and hose leading to the apparatus should be scrubbed with this solution. Then the parts should be rinsed with clear water, and given a second washing with an aqueous solution 50 per cent alcohol and allowed to dry.

The evidence that has been made available indicates quite clearly that the machine has demonstrated its worth in trained hands. The critical data consisted of many reports on the use of the resuscitator in the fields of surgery and obstetrics.

It must be pointed out, however, that the process of blowing oxygen into the lungs and aspirating it has a reverse effect on the circulation from that of normal respiration. Normal respiration tends to facilitate the exchange of gases in the lung capillaries. When the lung is inflated, even at very moderate pressures, circulation through the lung capillaries is retarded for an instant, since the blood pressure in these capillaries is very small. Stoppage here necessarily affects the entire circulation. However, periodic stops last only a moment, since the peak pressure (14 mm. of mercury) is maintained for only a short part of the cycle.

Another point should be borne in mind. While artificial respiration has been maintained by systems of this type in physiologic laboratories where experiments are performed on animals with the chest opened, the pressure required for adequate ventilation in such cases is much less than that required to distend the lung when the diaphragm must be forced down against the pressure of the abdominal contents and the bony thorax distended by pressure exerted by the lung from within.

In accepting the apparatus the Council wishes to stress two points, namely: (*a*) no artificial resuscitator or inhalator should replace the training of medical men and first aid men in the prone pressure method of resuscitation; (*b*) it is very important that this machine be used by well trained operators who have received their instruction from competent physicians.

The acceptance of this apparatus, therefore, is not to be regarded as a recommendation to abandon prone pressure methods of artificial respiration. In cases needing resuscitation the prone pressure method should be instituted immediately pending the arrival of any type of resuscitator, inhalator, or respirator, providing the patient's condition permits.

It is manifestly impossible to apply prone pressure artificial respiration in all conditions which arise in medical practice, as instanced in surgical operation on the abdomen when respiration fails. In such cases a mechanical device for maintaining artificial respiration over short periods may be very desirable. Operators who are trained to use the mechanical resuscitator should also be equally well trained in the prone pressure method of artificial respiration.

In view of its findings, the Council on Physical Therapy has voted to accept the E & J Resuscitator and Inhalator for inclu-

1. Resuscitator, an apparatus for revivifying, reviving or restoring from apparent death or from unconsciousness.
2. Inhalator, an apparatus for facilitating the breathing or drawing in of gas or a spray.

sion in its list of accepted apparatus, with an understanding of the limitations and hazards of positive pressure resuscitators, with the expectation that it will be used only by professional or other adequately trained personnel.

RESUSCITATION

A Comment by the Secretary of the Council on Physical Therapy

Historical documents record that man has tried innumerable methods, in one form or another, of reviving victims of asphyxia. Probably the earliest record of an attempt to resuscitate is in the Bible. Here it is said that Elisha brought back to life the son of a Shunamite woman by breathing into the mouth of the child.

We find also that in the early ages men employed burning and cutting of the skin, used boiling water, burning oil, whipping and noise as means of reviving the victim, as well as less drastic procedures, such as the application of heat by warm clay or ashes and warm poultices.[1] Counter shock, contrast baths, electrical stimulation, ducking in water, and blows on the soles of the feet and at the region of the heart are recorded. Two unusual methods were the drawing of a couple of teeth and the administration of wine or brandy. Of these two, if the patient was lucky enough to be revived, undoubtedly he preferred the latter rather than the former method. Fumigation has been used, that is, blowing tobacco smoke or charcoal fumes into the mouth or into the rectum. The rolling methods were tried; for example, rolling the patient over and over like a barrel, rolling him in a barrel or rolling him on a barrel. Manipulation, such as moving the arms in and out or up and down, working the legs, applying pressure alternately to the stomach and then to the chest or turning the victim back and forth from side to back are also recorded. Other methods were laying the patient face down or on his back and lifting his hips up and down, and countless other methods. Such were some of the practices of medical antiquity.

One method, placing the patient in a prone position and, among other operations, applying pressure to the small of the back, has survived. It is known as the Schafer prone pressure method. Careful investigation of the physiology involved has led to its acceptance and recognition.

When oxygen was discovered, it was used for resuscitation. At the present time a mixture of oxygen and carbon dioxide gas is an acceptable method, since investigation has shown that carbon dioxide stimulates the respiratory centers.[2]

Concurrently with some of the aforementioned methods, mechanical means were introduced in the sixteenth century. So we learn that Paracelsus of Switzerland in 1530 was the first to make use of the common fireside bellows for introducing air into the lungs of the apparently drowned person. In 1776 John Hunter improved the bellows for filling the lungs with fresh air and withdrawing exhaled breath from the patient. This method appeared to be so useful in the opinion of the Royal Humane Society of London that it was adopted by that organization in 1782. In 1911 the pulmotor appeared on the market. This was an automatic pumping device energized by the compressed gas within the tanks, which introduced gas into the air passages and sucked it out.

The report of the Council on Physical Therapy in this issue on the E & J Resuscitator and Inhalator precedes this item. It is energized by compressed gas stored in the two tanks in the carrying case. By a positive and negative pressure created at the mouth and nose within a face mask, gas passes back and forth within the air passages. The device automatically regulates itself to the size of the lungs and is provided with safety appliances. For the past seven years the Council on Physical Therapy has given careful consideration to mechanical resuscitating apparatus and has accepted the Drinker and Emerson respirators, both adult and infant size. The Council has also considered and accepted inhalators of various makes which provide an atmosphere of oxygen and carbon dioxide at the nose and mouth of the victim. These appliances, such as the H-H Inhalator and the Davis and the B-K Inhalators, are used in conjunction with the Schafer prone pressure method of resuscitation.

There follows a communication from Dr. Yandell Henderson and the Council's reply. Dr. Henderson is a recognized authority in the field of resuscitation and is a champion of the Schafer prone pressure method of resuscitation and one of the originators of the H-H Inhalator. He has opposed mechanical methods of the blow and suck type of resuscitator. One of his reasons is that the promotion of this kind of resuscitation will have a tendency to depreciate the value of the Schafer prone pressure method. In accepting the E & J Resuscitator the Council points out most emphatically that acceptance is not a recommendation to abandon the Schafer prone pressure method but that safety organizations, Boy Scouts, Red Cross and all other first aid groups should be carefully instructed in the use of this valuable measure. It is very important, the Council states, that all resuscitators and inhalators be used by well trained operators who have received their instructions from competent physicians.

As an indication of the care which the Councils of the Association take in consideration of products, the E & J Resuscitator is an excellent example. The Council on Physical Therapy has considered this product for a period of several years. During this time there have been numerous charges and countercharges received from several sources and in most cases the arguments were sincere. In such a situation the Council is not to be deterred from its cardinal principle—that it will not accept an apparatus for inclusion in its list of accepted apparatus until it is satisfied by the evidence and unless the manufacturer limits its claims to what the Council considers true and justified. The Council has spent a great deal of time in going over painstakingly the evidence which has been presented, which involves mechanical construction, principles, physiology and respiration, and other material.

2. Henderson, Yandell: Resuscitation, J. A. M. A. **103**:750 (Sept. 8), 834 (Sept. 15) 1934.

AN OPEN LETTER BY DR. YANDELL HENDERSON

To the Board of Trustees:—For some years past the American Medical Association has maintained a *Council on Physical* Therapy. Like the Council on Pharmacy and Chemistry, it is intended to afford the medical profession the technical advice that will maintain high standards of therapy and protect the public against harmful materials and methods. Yet in one of the most important fields of physical therapy—that of resuscitation—the influence of the Council, instead of being beneficial, is becoming extremely harmful. It is lowering standards and promoting methods and devices that will severely decrease the saving of life.

Three points require particular attention: 1. The Council on Physical Therapy is antagonizing a policy for general training in manual artificial respiration followed with marked success for many years by the American Red Cross. 2. It is approving apparatus that, if generally adopted, will seriously decrease the efficiency of the treatment of carbon monoxide poisoning and thereby largely increase the mortality. 3. It is tolerating and thereby virtually approving and promoting apparatus of the pulmotor type for application to the asphyxial newborn, which apparatus, if it works at all, administers a form of artificial respiration that tends rather to induce than to overcome atelectasis, and that in addition sometimes causes serious damage to the lungs.

I. Although I have no official authority to speak for the Red Cross, I have a reason for defending its methods of resuscitation, which I believe to be equally valid. Twenty-six years ago, in 1912, at the request of the director of the United States Bureau of Mines, the American Medical Association appointed a committee to investigate the subject of resuscitation from asphyxia by mine gases and, in particular, to recommend the best method of administering artificial respiration. The committee (generally referred to as the First Resuscitation Commission) included W. B. Cannon, chairman, G. W. Crile, Joseph Erlanger, S. J. Meltzer and myself. At the request of the National Electric Light Association this committee was enlarged by the addition of several electrical experts, including Elihu Thompson and A. E. Kennelly, to form the Second Resuscita-

tion Commission for the investigation of electric shock. Under both commissions we made very thorough investigations—among which I dealt particularly with manual artificial respiration; and on these investigations we based positive recommendations. These recommendations were at once adopted by the Bureau of Mines (Technical Paper 77, 1914), the United States Navy, the electric light industry and, most important of all, the American Red Cross. The chief recommendations were (1) the elimination of all mechanical appliances for giving artificial respiration under field conditions, and (2) universal training in the Schafer prone pressure method of artificial respiration. For the elimination of mechanical apparatus, of which four types were tested, several reasons were given: 1. At best such apparatus was found to be no more effective than the manual method. 2. A face mask frequently leaks and automatic apparatus often fails to operate as intended. 3. Experience proves that in any community where there is such apparatus the training in manual artificial respiration is neglected, the apparatus is sent for and the early moments of asphyxia, which are critical for the saving of life, are lost. 4. The form of respiration induced by the pulmotor, the appliance to which we devoted most careful consideration, was found to be distinctly unphysiologic and prone to induce atelectasis and to cause serious injury to the lungs.

In 1917 a third commission reviewed and generally confirmed these recommendations (*Science* **48**:563, 1918). Among its members were S. J. Meltzer, chairman, E. F. Du Bois, D. L. Edsall, W. H. Howell, Reid Hunt, C. A. Lauffer, J. W. Schereschewsky, G. N. Stewart, E. B. Vedder, C. H. Frazier and Yandell Henderson, and for the electrical industry Elihu Thompson, A. E. Kennelly, Wills Maclachlan and C. B. Scott. And in 1922 a fourth commission (*J. Indust. Hyg.* **6**:125, 1923), which included C. K. Drinker, chairman, W. B. Cannon, D. L. Edsall, H. W. Haggard, L. J. Henderson, Yandell Henderson, W. K. Lewis, F. W. Peabody and R. R. Sayers also disapproved mechanical artificial resuscitation devices, particularly those of the pulmotor type, and advocated general training in manual artificial respiration for use in such emergencies as drowning and electric shock. It was under this fourth commission that the treatment of carbon monoxide asphyxia by inhalation of a mixture of carbon dioxide with oxygen was developed and introduced (Drinker, C. K.: Carbon Monoxide Asphyxia, Oxford University Press, 1938. Henderson, Yandell: Adventures in Respiration, Baltimore: Williams & Wilkins Company, 1938).

Largely under the influence of the Red Cross, based on the reports of these commissions, more than 13 million policemen, firemen, boy scouts and others have been trained to administer manual artificial respiration and many lives are now thereby saved. It is deplorable that the influence of the Council on Physical Therapy should now be exerted against the recommendations of these commissions and against such training. Yet this influence is becoming effective, for a letter recently received asks me whether I advocate "resuscitators," by which name devices of the pulmotor type are now called, and notes "a strong tendency toward the use of resuscitators and elimination of the prone pressure method."

II. Having myself formerly served as a member of the Council on Physical Therapy, and having from time to time corresponded with its Chairman and Secretary, I have been led to conclude that the attitude of the Council in regard to the recommendations of these four commissions is not really one of opposition. It is merely one of ignorance. The Council is evidently unacquainted with the work that was done under these commissions. None of the members of the Council are specialists in the subject of resuscitation nor do they seem to realize that resuscitation is a very specialized subject. Each device that is submitted to the Council is merely referred to a referee; and while I was in the Council the reports of these referees, of whose names I was never informed, showed that their anonymous authors in many cases lacked both the general knowledge and the practical experience that the evaluation of any device in the field of resuscitation requires.

I will instance two such devices. One is an inhalator for the treatment of carbon monoxide asphyxia. When I wrote to the Secretary of the Council in regard to this device he replied "The Council has accepted the S. O. S. Inhalator put out by the Oxygen Equipment and Service Company of Chicago. This device, as you know, looks very much like other inhalators that have been accepted by the Council." Yet, in fact, this device is essentially different from and inferior to the inhalators now used by the rescue crews of city fire departments and other organizations. Those inhalators are particularly designed to administer a mixture of carbon dioxide with oxygen and to promote the rapid elimination of carbon monoxide by the avoidance of all rebreathing. This inhalator, on the contrary, can use only pure oxygen, for if carbon dioxide were added the small supply of oxygen in its little cylinders would be almost immediately exhausted. And it expressly provides for at least partial rebreathing, which will correspondingly prevent the elimination of carbon monoxide and prolong the asphyxia. It is, in fact, simply an oxygen inhalator like those used twenty years ago, before the modern treatment of asphyxia was developed.

The referee on this device was evidently unaware of the developments of recent years in regard to asphyxia and its treatment. And the Council in accepting his report either showed a similar degree of unawareness or else neglected to give the matter any serious consideration. The result of the approval of this device will be the loss of many lives that could and should be saved.

I venture therefore to suggest that, if the Council cannot devote the requisite knowledge, care and time to the examination of devices in the field of resuscitation, it could at least follow the lead and adopt the recommendations of another organization, namely the committee on safety of the American Gas Association. That association includes practically all of the city gas companies and is therefore vitally interested in holding the mortality from carbon monoxide asphyxia to a minimum. Its committee on safety does apply modern knowledge to this field and does devote the requisite time and care to its recommendations to afford the public the protection that it needs.

The other device to which I refer is the E & J Resuscitator. This device has been before the Council for about five years during which time its sales agents have continually claimed that it was about to be approved. And as two advertisements of it have appeared in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION (a full page advertisement on June 25, 1938, and previously a smaller one on May 7), and as it has been exhibited at the annual meeting of the Association, a formal approval would scarcely have been more effective in foisting this device on hospitals, bathing beaches and various other agencies concerned with resuscitation.

Yet this so-called "resuscitator" is to all intents and purposes simply a pulmotor under another name. All the objections that applied to the pulmotor apply equally to this device, and it is needless to rehearse them. But one additional objection must be mentioned. It arises from the interest that has developed in recent years in regard to the asphyxia and resuscitation of the newborn. The lungs at birth are in a state of atelectasis, and even in the normal child they are only gradually dilated. It should be obvious then that in the treatment of asphyxia of the newborn nothing should be done to collapse them. Yet in the artificial respiration produced by this "resuscitator" and similar apparatus of the pulmotor type not only inflation but also deflation is applied. Its action, as should be expected, tends therefore not to promote but rather to oppose the dilatation of the lungs and often causes serious injury, demonstrable at autopsy. After application of this apparatus the survival of the baby is in fact rare. How injurious the E & J Resuscitator may be is shown in a recent paper by Dr. F. N. Coryllos. Dr. Coryllos was himself a supporter of the value of this device for use in connection with thoracic surgical operations. Nevertheless he found that, when healthy dogs were submitted to artificial respiration by means of it, the lungs after a few hours were in several cases too far collapsed and damaged for the animals to survive (*Surg., Gynec. & Obst.* **66**:698 [April] 1938).

The case against this device could scarcely be clearer or stronger. Yet year after year goes by and the Council still hesitates to approve or disapprove while the device appears to have an increasing sale at bathing beaches and in the maternity wards of hospitals.

III. If these two devices stood by themselves, the case against them would scarcely justify so unusual a motion as this appeal over the heads of the Council on Physical Therapy to the Board of Trustees of the American Medical Association. But in fact there is probably no subject other than that of perpetual motion apparatus that exercises so strong a lure for ignorant inventors as that of restoring the dead to life. There is certain to be in future, as in the past, a long succession of devices invented for this purpose. And it is of literally vital importance that, if there is to be a Council on Physical Therapy and it is to pass on such devices, it should be competent and use competent means and agents. In particular, it should free itself from the popular but fallacious assumption on which the invention of all pulmotors, resuscitators and other artificial respiration devices is based that the restoration of respiration in a nonbreathing patient is like starting the motor of an automobile: in other words, that if the thorax is put through the movements of breathing by vigorous "cranking" it will pick up the rhythm and continue to run. In fact, on the contrary, natural respiration is induced only by chemical not mechanical conditions; and those conditions are the supply of oxygen and carbon dioxide through the blood from the lungs to the respiratory center in the base of the brain. It is for this reason that the inhalators used by the rescue crews as adjuncts to manual artificial respiration on cases of submersion and electric shock are superior to all apparatus of the pulmotor type. The fact that such apparatus is able to inflate and deflate a rubber doll is impressive only to those who are untrained in the physiology of respiration.

YANDELL HENDERSON, PH.D., New Haven, Conn.

THE COUNCIL ON PHYSICAL THERAPY VOTED TO ADOPT THE FOLLOWING REPLY.

HOWARD A. CARTER, Secretary.

REPLY TO THE OPEN LETTER FROM DR. YANDELL HENDERSON

The Council on Physical Therapy has devoted much time to the entire subject of resuscitation in relation to all types of respirators, resuscitators and inhalators.

Dr. Henderson's first charge is that the Council on Physical Therapy "is lowering standards and promoting methods and devices that will severely decrease the saving of life." The Council has on many occasions emphasized the importance of the Schafer prone pressure method of artificial respiration. In the booklet "Apparatus Accepted" the Council describes and promotes this life-saving measure. The Council will continue to publicize this important method and will vigorously combat any effort on the part of an institution or organization to discard it.

Dr. Henderson's second charge is that the Council "is approving apparatus that, if generally adopted, will seriously decrease the efficiency of the treatment of carbon monoxide poisoning and thereby largely increase the mortality." The Council has accepted the Drinker and Emerson types of respirators, which are of unquestionable value especially in infantile paralysis: the H-H Inhalator, the B-K Inhalator, and the Davis Inhalator, which functions on the same principle as the H-H Inhalator. All of these appliances have been on the Council's accepted list for several years.

Further on in the letter Dr. Henderson refers to the S. O. S. Inhalator. Although the Council has given consideration to this product, it has not released a report of acceptance on this unit and does not expect to until further evidence is submitted by the manufacturer to substantiate certain claims made. At present, therefore, this product stands neither accepted nor rejected. The firm has been asked to submit further evidence of its efficacy as, for example, a report of animal experiments definitely showing the amount of carbon monoxide present in the bag when the inhalator is being used in resuscitation.

The third charge is that the Council "is tolerating and thereby virtually approving and promoting apparatus of the pulmotor type for application to the asphyxial newborn, which apparatus, if it works at all, administers a form of artificial respiration that tends rather to induce than to overcome atelectasis, and that in addition sometimes causes serious damage to the lungs." Following this charge Dr. Henderson gives a detailed study of appointments of commissions by the Red Cross, American Medical Association, National Electric Light Association and engineering societies and a report of the findings of these commissions. He intimates that the Council is not familiar with the work of these commissions or their results and definitely states that the Council has no member or members familiar with the subject of resuscitation—"nor do they seem to realize that resuscitation is a very specialized subject." He further condemns the Council's method of referring these appliances to referees "of whose names I was never informed. . . ."

In reply the Council would state that it has made exhaustive studies of the E & J Resuscitator (the product to which Dr. Henderson refers later on in his letter) to satisfy itself that the apparatus was not of the old type pulmotor. The Council is thoroughly familiar with the work of the commissions to which Dr. Henderson refers and also with their reports concerning the Schafer prone pressure method of resuscitation, to the use of the inhalator type of apparatus and to the condemnation of the old type pulmotor.

Investigation indicates that the S. O. S. Inhalator has been used by several fire and police departments in the vicinity of Chicago with success. This product, therefore, is definitely a product in competition with accepted inhalators.

Furthermore, the Oxygen Equipment and Manufacturing Company is refilling tanks with carbon dioxide and oxygen mixture, which is the mixture furnished by the Mine Safety Appliances and marketed under the trade name of "Carbogen." (Carbogen is not accepted by the Council on Pharmacy and Chemistry.) The refilling of tanks has reduced the cost of this mixture, especially in the vicinity of Chicago. Furthermore, one of the charges of Dr. Henderson, that is, that the tanks are too small and that "its little cylinders would be almost immediately exhausted," is denied by the manufacturer, since the tanks are one-half the size of those furnished by the Mine Safety Appliances Company and other firms. The firm points out that a user of this equipment can lay in a supply of tanks and can, in fact, connect the unit to a large sized oxygen tank if the occasion arises.

The E & J Resuscitator and Inhalator was first discussed in Queries and Minor Notes in THE JOURNAL Nov. 16, 1929, page 1583. The reply condemned the E & J Resuscitator. In February 1934 the E & J Resuscitator and Inhalator was submitted to the Council for consideration. After investigation, a report of rejection was referred to the firm. The E & J Manufacturing Company pointed out that in its opinion the report was in error and submitted arguments that convinced the majority of the Council members that further investigation was indicated.

A leading chief surgeon of a large corporation, who had considerable experience with the E & J Resuscitator and Inhalator, not only wrote to the Council but made a trip to Chicago to interview the Chairman, the Secretary and one other member of the Council. He presented evidence showing that a number of these resuscitators were in use in various plants of which he was in charge and that they had rendered definite life-saving service in many instances.

The Council has selected specialists of known reputation to serve as referees for all inhalators and resuscitators. Since 1935 at least four referees, specialists in the field, have investigated independently the E & J Resuscitator and Inhalator and made reports to the Council.

During the year 1936 the E & J Manufacturing Company submitted evidence to the Council accumulated by the late Dr. Pol Coryllos. Dr. Coryllos's paper was published in *Surgery, Gynecology and Obstetrics* in April 1938 but the substance of the report, together with motion pictures, was furnished the Council in 1936. The work of Dr. Coryllos, in the opinion of the Council, was well done and convinced the members that the E & J Resuscitator and Inhalator was a safe appliance, that it had real life-saving value and that an injustice would have been done to its manufacturer if the original report of rejection had been published.

Thirty-nine different physicians of recognized professional ability were asked by the Council to submit reports of cases treated with the E & J Resuscitator. The vast majority of these reports were highly favorable to the resuscitator in spite of the fact that many of the patients were practically moribund at the time when resuscitation was initiated.

Finally, the Council had submitted to it a report of Dr. D. Ben Martinez, published in THE JOURNAL Aug. 14, 1937, in which he reported 500 cases of resuscitation of the newborn; the E & J Resuscitator was used in these cases.

A large midwestern fire department uses the E & J Resuscitator and Inhalator in preference to inhalators, giving as reasons: 1. Inhalators require at least two, or preferably three, men to operate, while the E & J Resuscitator requires but one man. 2. Inhalators require more space to use than does the resuscitator. 3. The E & J Resuscitator is more practical when used on a pregnant woman or on a person with broken ribs. 4. Better results are obtained with the E & J Resuscitator. The fire department has defended its use of the E & J Resuscitator in the face of opposition. It has convinced its city's health department that the resuscitator is efficient. The department had three E & J Resuscitators in 1931 and in 1934 purchased seven more and now it has twelve. Squads are well trained in the use of this apparatus and are also well trained in the use of inhalators and the Schafer prone pressure method. They demonstrated completely their ability to use this apparatus to the complete satisfaction of a committee of the Council.

Therefore, in reply to Dr. Henderson's charges that the Council on Physical Therapy is not familiar with resuscitation, that it depends simply on the statements of referees of questionable ability, and that it is accepting apparatus that will "lower standards and promote methods and devices that will severely decrease the saving of life," the Council submits the foregoing information to demonstrate the thoroughness of its investigation of the E & J Resuscitator and the effort the Council has put forth to avoid the loss of a single life through any of its published actions.

COUNCIL ON PHYSICAL THERAPY.
HARRY E. MOCK, M.D., Chairman.
HOWARD A. CARTER, Secretary.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. PAUL NICHOLAS LEECH, Secretary.

THE PRESENT STATUS OF TESTOSTERONE PROPIONATE: THREE BRANDS, PERANDREN, ORETON AND NEO-HOMBREOL (ROCHE-ORGANON) NOT ACCEPTABLE FOR N. N. R.

Within the past few months extravagant claims for the action of the male sex hormone testosterone have appeared in professional and lay publications. The naturally popular appeal of this substance has aroused wide interest with the aid of ample newspaper publicity. It may eventually prove that this substance, testosterone, or its esters will be a valuable addition to our armamentarium of glandular therapy; but it is the Council's belief that many claims for it have been grossly exaggerated. The male hormone has only recently been made available for clinical use and there have already been widespread announcements of its remarkable effects, both physical and psychic, which are a long way from actually being established. In view of the uncontrolled advertising and publicity, the Council is issuing this report on the status of the male hormone.

Testosterone, the male or testicular hormone, was first isolated from bulls' testes. It is not to be confused with androsterone, which appears in human urine. After establishment of its formula, Ruzicka was able to prepare the identical substance synthetically. It is generally accepted that testosterone is the substance secreted by the interstitial cells of the testes and that its function is the induction and maintenance of the secondary sex characteristics of the male. Fatty acid esters of testosterone are more slowly absorbed from the site of injection than the free testosterone. It apparently acts by simulating gonadal activity and in this manner the physiologic response has been observed to improve considerably. The most widely used ester at present is the propionate of testosterone.

In the clinical use of most endocrine preparations it seems to be a fairly consistent rule that the response to any hormone is most efficient and satisfactory when there already exists a clearly defined deficiency of that substance. This rule holds quite well for the male hormone and aids in indicating the use of this substance. Therapy has been attempted in the following conditions and, while the treatment of all of them is still in the experimental stage, it appears that results are promising in only a few.

EUNUCHOIDISM

The most careful studies in the clinical use of testosterone have been made in cases of eunuchoidism.[1] The cases of testicular deficiency reported by these workers were well defined. The testes were either absent or atrophic or else retained in the abdomen. The penis was underdeveloped and the prostate hypoplastic. Erections were infrequent or feeble and libido was negligible. Other signs and symptoms were typical: deficiency of pubic, facial and body hair, fine boyish skin and high pitched voice. Psychic conflicts were frequent, rendering the patient anxious, depressed and apathetic with a feeling of social inferiority. Occasionally the patients suffered from hot flashes, irritability and depression, symptoms typical of the climacteric.

The response to testosterone propionate was reported to be excellent. Within a short time sexual desire was initiated, erections became frequent and satisfactory, and nocturnal emissions occurred. After several months of continuous treatment the hair growth became heavier, the skin reverted to the adult type and the voice changed to a lower pitch. The prostate in a few cases enlarged somewhat and the penis approached normal dimensions. The psychic responses were no less spectacular. Relief from climacteric distress was complete, self assurance returned and emotional stability was manifested. Some of the beneficial results on the psyche may have been merely the reflection of the patient's pleasure in the physical changes and the sensations of sexual activity.

The dosage required to bring about these changes varied considerably. According to Kenyon,[2] from 7 to 21 mg. of testosterone is metabolized and lost daily in the urine and on these grounds he believes that 25 mg. daily is a reasonable amount for injection. Results have been obtained with smaller doses, but the preponderance of opinion indicates that from 75 to 150 mg. per week is necessary for complete replacement therapy. It cannot be stressed too strongly that the desired effects persist only as long as the therapy is maintained. No cure should be expected and regression of all beneficial changes takes place soon after the last injection. It is obvious, therefore, that androgenic therapy is an expensive procedure. Although the experimental treatment of eunuchoidism has proved successful, social and economic factors are formidable obstacles when this therapy is applied to the private patient. The careful selection of cases and the use of great caution are demanded for the proper treatment of this condition.[2a]

2a. A well known news weekly has recently given wide publicity to the method adopted by Foss in England of administering to patients testosterone propionate by inunction. Following this work, several firms have put on the market ointments containing testosterone propionate. Foss and also Parkes administered to several eunuchs doses of from 20 to 50 mg. of testosterone propionate in about 2 cc. of ointment daily in order to obtain satisfactory results. The products marketed in this country contain only 2 mg. of the androgen per cubic centimeter of ointment. It is apparent, therefore, that to administer the appropriate amount of active material the patient must anoint himself with from 10 to 25 cc. of ointment daily. This would, of course, make quite a mess.

IMPOTENCE

The great majority of young men who complain of impotence suffer from so-called psychic impotence. The few cases reported in the literature which were treated with androgens did not respond very favorably.[3] This is in line with the rule just stated that the male hormone works best when there exists a deficiency. The males with a psychic disturbance have normally functioning testes and the additional male hormone provided by injection does not appear to correct this disturbance. Transitory improvement reported in several cases is probably the result of suggestion. There is no evidence that testosterone propionate has an aphrodisiac action in males with normal testicular function.

SENILITY

It appears that many pharmaceutic firms would have one believe that in the ampule of testosterone propionate lies the Fountain of Youth. The few reports in the literature of attempted rejuvenation are not at all promising. Laroche and Bompard[4] injected several aged men with this material and failed to improve their sexual powers appreciably. Apparently the action of male hormone on the masculinity of an individual is effective only within a certain age limit. Other factors, nervous or circulatory, probably play a role in the mechanism of erection and their absence in elderly males may prevent the response to testosterone. Premature impotence may well fit into this category, but sufficient data are not at hand from which conclusions may be drawn. The involutional melancholia of males, for which testosterone has been suggested, has not been subjected to adequate trials to justify androgenic therapy other than on an experimental basis.

STERILITY

It is known that testosterone propionate will maintain spermatogenesis in the hypophysectomized rat, but once tubular degeneration has set in, it is unable to stimulate sperm formation. There is apparently some species difference in the response of the testes to androgens. Wells and Moore have shown that injections of male hormone stimulate spermatogenesis in the ground squirrel, while Moore and Price and others have demonstrated an atrophy of the testes in similarly treated adult rats. There is little clinical evidence that this substance is of any use in human male sterility. The few cases of therapeutic success reported in the literature certainly do not warrant the use of androgens in this disorder at the present time.

PROSTATISM

There are a number of reports dealing with the use of male hormone in prostatism.[5] The impression seems general that improvement is evidenced in most cases on this type of treatment. In long standing cases of complete or incomplete retention there was a return of spontaneous urination soon after the first few injections. Frequency and nocturia decreased. The amount of residual urine diminished and the general condition of the patient improved following amelioration of the distress of prostatism. In most cases of prostatic hypertrophy there was no decrease in size of the organ. Laroche and his co-workers[6] obtained in several cases a diminution in size of the prostate, but they were careful to point out that this was due probably to the disappearance of congestion and inflammation and not due to any regression of the prostatic adenoma. In this regard it seems ill advised to describe, as several authors do, the androgenic therapy as treatment of prostatic hypertrophy, when no evidence is at hand that the excess tissue is appreciably affected. As a matter of fact, it has been recently shown that "the injection of 285 to 1,125 mg. of testosterone propionate in from 12 to 95 days results in no significant restoration of the involuted prostate of presenility and in no observable alteration in the histological appearance of the tissues formed in benign hypertrophy."[7] The actual mode of action of the androgen is unknown, the improvements being due possibly to an improvement in sphincter action, or relaxation of spasm, an increase in bladder tone or an attenuation of prostatic congestion.

On the other hand, Clarke[8] believes that conservative treatment is just as effective. He has followed ninety-three cases of prostatism and shown a large number of satisfactory responses on instrumentation alone. He suggested that a period of five years is necessary before results of endocrine therapy can be reliably assessed. The view taken by Riches[9] is an admirable one and strikes a note of caution in accepting this newer treatment of prostatism:

> The natural history of prostatic obstruction is one of frequent remissions and relapses, and many vaunted remedies in the past have owed their ephemeral reputations to their use at a time when acute congestive retention has just been relieved by catheterization. After a period perhaps of years it has been found that the prostatic enlargement has steadily progressed and has ultimately required operation when the patient is older and less fit and his kidneys have begun to fail. Herein lies the greatest danger of treatment by male hormone and it must be emphasized that all such treatment is still in the experimental stage, and is, therefore, only justified in patients who are not so ill as to need active surgical treatment or are too ill to stand much chance of surviving such treatment. The field for experiment is thus greatly reduced and the assessment of results is made difficult by the normal remissions and relapses incident to the disease.

CRYPTORCHIDISM

Hamilton[10] has induced descent of the testes in immature monkeys by means of testosterone propionate injections. He has also obtained these results in cryptorchid boys and has suggested that androgens may be of value in the differential diagnosis of obstructive and nonobstructive cryptorchidism. By administering such therapy, the physician need not wait until puberty to know whether the testes will descend spontaneously. In Hamilton's opinion, male hormone may also aid in the surgical treatment of undescended testes. These recommendations are attractive, but approval must await further clinical trial.

On the other hand, Kunstadter[11] warns against the induction of precocious puberty in boys by means of androgens. He observed some patients who were relatively sensitive to the androgenic substance, developing definite masculine traits after the administration of a moderate amount of this material. He considered these reactions harmful to the patient, especially from the psychologic standpoint. There have been several cases reported in the literature in which boys on androgenic treatment have resorted to masturbation and other undesirable behavior. It is highly important to remember that normal puberty varies considerably in its time of appearance. The diagnosis of hypogonadism in boys should be made with reserve and the endocrine treatment on the presumption of this condition should be accordingly avoided.

GYNECOLOGIC CONDITIONS

Estrous cycles of rodents have been suppressed by means of testosterone administration on the basis of its similarity to progesterone. In the monkey, Zuckerman[12] inhibited menstruation and obtained involution of the endometrium and ovarian atrophy by injections of androgenic substance. Inhibition of menstruation has also been obtained in the human being by Hartman[13] and by Papanicolaou and his co-workers.[14] Several

investigators[15] have treated cases of functional menorrhagia with testosterone propionate and have been able to decrease the uterine bleeding. Hundreds of milligrams of the material was usually necessary to produce the desired results. Desmarest and Capitain[16] have reported beneficial results in mastopathy with somewhat smaller doses (100-200 mg.). Other conditions in which male hormone therapy has received trials are the menopause, undesired lactation and dysmenorrhea. Such treatment should be reserved for the present for the specialist in this field, since very little is known as to the proper handling of these cases except that to obtain desired results in most cases it appears necessary to employ tremendous doses of testosterone propionate. Very little is known regarding the permanence of these results. The practicability of this therapy is, therefore, rather doubtful just now. Furthermore, a definite harm is risked when male hormone is administered to females. Greenhill and Freed[17] have induced a significant degree of virilism in women treated with this substance for certain gynecologic disorders including hirsutism and low voice. Other undesirable reactions may eventually be demonstrated.

MISCELLANEOUS

There are other conditions for which androgenic therapy has been suggested, such as atrophic rhinitis, acne and gynecomastia. The available data in such cases are either absent or inadequate to justify any claims of usefulness.

CONCLUSIONS

According to our present knowledge, testosterone propionate shows promise in only a few conditions. Careful studies have shown that it is adequate replacement therapy in true testicular deficiency (eunuchoidism), but the applicability of this therapy in actual practice is still undetermined. Its employment in cases of cryptorchidism, though not well established clinically, is on a sound physiologic basis. The relief so often elicited by testosterone propionate in cases of urinary retention due to prostatism is quite gratifying, but a reliable evaluation of the benefits or dangers of this treatment must await extensive experimentation over a period of years. All other claims are either exaggerated or immature and should be disregarded until substantial evidence becomes available on which to evaluate them.

The Council deferred further consideration of testosterone propionate until it has been properly evaluated by ample clinical experience.

On the basis of the foregoing report and without a detailed investigation of the advertising policies of the firms which market this substance, the Council also declared the marketed brands of testosterone propionate, namely Perandren (Ciba Pharmaceutical Products, Inc.), Oreton (Schering Corp.) and Neo-Hombreol (Roche-Organon) (Hoffmann-LaRoche, Inc.), unacceptable for inclusion in New and Nonofficial Remedies.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLE HAS BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

RACÉPHEDRINE HYDROCHLORIDE (See THE JOURNAL, April 1, 1939, p. 1257).

Racéphedrine Hydrochloride-Gane's Chemical Works, Inc.—A brand of racéphedrine hydrochloride-N. N. R.

Manufactured by Gane's Chemical Works, Inc., New York. No U. S. patent or trade mark.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

CELLU BRAND LOGANBERRY JUICE

Distributor.—Chicago Dietetic Supply House, Inc., Chicago.

Description.—Canned loganberry juice packed without added sugar.

Manufacture.—Good quality loganberries on which no spray material has been used are thoroughly washed, sorted for spoilage and foreign matter, preheated and pressed through ordinary press cloth. The juice is run into cans which are sealed and heat processed.

Analysis (submitted by distributor).—Moisture 90.0%, total solids 10.0%, ash 0.4%, fat (ether extract) 1.0%, protein (N × 6.25) 0.2%, crude fiber 0.02%, carbohydrates other than crude fiber (by difference) 8.4%, invert sugar 8.3%, sucrose 0.1%.

Calories.—0.4 per gram; 11 per ounce.

RED & WHITE BRAND FLOUR (BLEACHED)

Distributor.—Slocum-Bergren Company, Minneapolis.

Manufacturer.—Russell-Miller Milling Company, Minneapolis.

Description.—A long patent, bleached flour milled from hard winter wheat.

Manufacture.—Hard winter wheat is cleaned, washed, dried, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, page 2210. The flour is bleached with 13 Gm. of a mixture of benzoyl peroxide and calcium phosphate and 2 Gm. of nitrogen trichloride per barrel.

Analysis (submitted by manufacturer).—Moisture 13.5%, total solids 86.5%, ash 0.5%, fat (ether extract) 1.5%, protein (N × 5.7) 11.2%, sucrose 1.3%, reducing sugar as invert sugar 1.7%, crude fiber 1.0%, carbohydrates other than crude fiber (by difference) 72.3%.

Calories.—3.48 per gram; 99 per ounce.

MILLER'S BRAND SPAGHETTI, MACARONI AND MACARONI PRODUCTS

Manufacturer.—Miller's Food Products, Inc., Los Angeles.

Description.—Spaghetti and macaroni, of various sizes and shapes, prepared from durum wheat semolina and water.

Manufacture.—Durum semolina and water in formula proportions are mechanically mixed and kneaded. The resulting dough is forced through a pressing and cutting machine and the pieces are dried and packed.

Analysis (submitted by manufacturer).—Moisture 11.4%, total solids 88.6%, ash 0.6%, fat (ether extract) 0.3%, protein (N × 5.7) 12.4%, crude fiber 0.4%, carbohydrates other than crude fiber (by difference) 74.9%.

Calories.—3.52 per gram; 100 per ounce.

CRADLE BABY BRAND STRAINED AND SEEDLESS APRICOT JAM

Manufacturer.—Glaser, Crandell Company, Chicago.

Description.—Canned strained apricot jam sweetened with sucrose. The jam may contain small amounts of added acid or pectin or both.

Manufacture.—Canned California apricots which conform to the specifications of the manufacturer are softened and subsequently treated as described for Cradle Baby Brand Strained and Seedless Fig Jam (THE JOURNAL, March 18, 1939, p. 1071).

Analysis (submitted by manufacturer).—Moisture 30.4%, total solids 69.6%, water insoluble solids 0.9%, water soluble solids 68.7%, ash 0.4%, protein (N × 6.25) 0.4%, crude fiber 0.3%, carbohydrates other than crude fiber (by difference) 67.7%, acidity 0.8%.

Calories.—2.72 per gram; 77 per ounce.

THE CASE OF BRINKLEY VS. FISHBEIN

PROCEEDINGS OF A LIBEL SUIT BASED ON AN ARTICLE PUBLISHED IN *HYGEIA*

On March 22 in the District Court of the United States for the Western District of Texas began the trial of the case of *John R. Brinkley* v. *Morris Fishbein,* based on an article published in *Hygeia,* entitled "Modern Medical Charlatans." The judge was the Honorable Robert J. McMillan; the attorneys for the plaintiff, Messrs. Morriss & Morriss of San Antonio and Phil Foster of Del Rio; the defendant was represented by Messrs. Loesch, Scofield, Loesch & Burke of Chicago, Brooks, Napier, Brown & Matthews of San Antonio, and Boggess, LaCrosse & Lowrey of Del Rio, Texas.

The case attracted much attention, particularly in Del Rio, the home of Brinkley. The following statement by Millard Cope in the San Angelo (Texas) *Standard-Times* gives the setting of the stage:

"Inwardly, however, Del Rioans are hoping for a victory for Dr. Brinkley because they have not forgotten what he and his hospital meant to Del Rio when he performed his operations in Roswell Hotel here.

"He maintained a monthly pay roll estimated at between $17,000 and $20,000 before moving the hospital to Little Rock, Ark. That meant plenty to business in Del Rio.

"The manager of one of Del Rio's largest department stores said that firm lost a thousand dollars a month in accounts when the Brinkley hospital was moved. Postal receipts, so often used as a business barometer, reflected a decline when Dr. Brinkley's hospital was moved. In 1937, for instance, postal receipts aggregated $54,167.54. (That was the year he testified as having grossed $1,100,000.) Last year, however, with the Brinkley hospital in Little Rock, receipts dropped nearly a fifth to $44,399.22.

"SAYS DEL RIO SUFFERED

"'Del Rio suffered its greatest loss when Dr. Brinkley moved to Little Rock.' declares H. Lippe, whose picture and curio business, he says, has shown a heavy loss.

"Over at the Del Rio National Bank, J. A. Walker reminds that any city the size of Del Rio will suffer when it loses such a pay roll as Dr. Brinkley maintained. 'Of course, Del Rio was getting along before we ever heard of Dr. Brinkley, and we'll still go along, but it's obvious that the hospital is missed.'

"The Chamber of Commerce, through James C. Netts, secretary, admits there are some vacant houses and waiting hotel and tourist camp rooms, which were filled when Dr. Brinkley attracted thousands of persons to his hospital annually. Some of the tourist camps were built to accommodate the influx of oldsters.

"Obviously, the Roswell Hotel, used by Dr. Brinkley as his hospital, is missing the patients and guests, drawn magnet-like to its registration desk. F. H. Childs, the manager, isn't experiencing so many full houses as before.

"Wherever one goes in Del Rio, virtually the same story is given. What city of 10,000 wouldn't miss a $20,000 pay roll every month, plus spendings of thousands who came seeking a more potent sex life? . . ."

In his article Mr. Cope gives the following description of Dr. Brinkley:

"Del Rioans have a kindly feeling for Dr. Brinkley for a lot of reasons other than the pay roll he maintained when he operated the hospital here. He maintains his home in Del Rio, a palace sort of Spanish-type architecture centered in a 12 acre tract. It's prettier at night, because the two lighted fountains are turned on, a dozen colors changing all the time as lights are thrown on water squirting 30 feet into the air. One has no difficulty in knowing its owner. The name "Dr. Brinkley" is in large letters on the gates to the blue-painted concrete drives, and the name flashes in neon on the fountains at night.

"Some say he has as much as $200,000 invested in the place. Inside, visitors see furniture brought over from France, imported tapestries, carpets, and works of art. There is an $11,000 pipe organ. In one of the rooms is a collection of perfumes which he has collected as a hobby and which now is valued at more than $5,000. He collects a variety of things. He's just as likely to return from a world cruise with a collection of cameras as flamingoes, freak dogs or shotguns.

"The unusual Dr. Brinkley has a flair for the unusual.

"MAKES NUMEROUS DONATIONS

"He thought the high school should have a business course and donated the typewriters, desks and other equipment. He provides candy and fruit for every child in Del Rio at a Christmas party each season. When the Rotary Club sought to increase its student loan fund, he offered to match it, reaching into his pocket to display three $500 bills. He offered $25,000 cash if the city would cause a similar amount for a public library to be raised.

"Though he built radio station XERA at Villa Acuna, Mexico, across the Rio Grande, he now denies any ownership, explaining he sold his interest and buys time as any other advertiser who broadcasts.

"He is driven to the court trial each morning by Mrs. Brinkley in a long, specially built body Cadillac, its color as bright a red as any fire truck, on which the name "Dr. Brinkley" is inscribed in 13 places, from the hub caps to the trunk. She stops the car at the curb, they kiss, and he's met by a group of admirers as he walks toward the federal building.

"A FORTUNE IN DIAMONDS

"Nattily attired, his close-cropped Van Dyke neatly trimmed for his appearance in court, and with diamonds flashing on his fingers, a tie-clasp and in a lodge emblem across his vest, Dr. Brinkley reflects some of the wealth he has acquired. The diamond in the ring on one finger is 14 carats, he says. On the other hand is a smaller one. There's a line of big ones in the tie clasp worn above the top button of his vest. Some estimate he may have spent as high as $100,000 for them. He has bought diamonds for Mrs. Brinkley, too. . . .

"Transportation is not much of a problem for Dr. Brinkley. He goes by land, air or water. He literally has a fleet of high-powered automobiles. There is a Lockheed Electra monoplane, with pilot and co-pilot, a 12-passenger ship for which he paid $58,000 and then added more than $20,000 worth of extras.

"ADMIRAL OF THREE YACHTS

"He's an admiral in his own right, owning three yachts. A picture of Dr. Brinkley in his private admiral's uniform hangs in Editor Travelstead's office. It is autographed: 'To Warrior Travelstead from Fighting Admiral Brinkley.' He would have bought another yacht, but the $1,000,000 price, he thought, was a little steep. It was the vessel on which abdicated King Edward VIII and the former Wally Simpson honeymooned in the Mediterranean. He had an associate contact a London broker as to the price.

"Hearing of the plight of orchard owners in the Rio Grande Valley in not being able to dispose of their fruit, he decided to buy an orchard. He passed up dividends for a few years by setting out new, choice trees. Now, his output is contracted. The grapefruit Dr. Fishbein ate Saturday morning in the Roswell Hotel came from the Brinkley orchard. . . .

"Judge R. J. McMillan's oblong little court room in the federal building is filled an hour before each day's trial begins, but that doesn't mean there is much of a crowd on hand. Its seating capacity is less than 100, and some twenty-five or thirty form a waiting line outside.

"A CLASS TO THE TRIAL

"The Del Rio school civics class was taken to one of the court sessions by its teacher, Miss Mary Louise Nelson. It prompted the remark that it should have been the physiology class. Another suggested taking the vocational agriculture class, referring to the goat glands.

"Judge McMillan keeps the strictest of order and there hardly has been a witness or attorney whom the judge has not called down in some manner. . . .

"Members of the jury represent varied professions, with ranching, as might be expected, predominating. They are: J. D. Harwood, Bracketville ranchman; Daniel Pedrotti, Del Rio merchant; H. D. Dick, Knippa farmer; Wilson Bonner, Dryden ranchman; William Paysinger, Batesville ranchman; L. G. Nunn, Uvalde bookkeeper; H. B. Cummings, Reagan Wells farmer; I. Hayes Cavender, Con Can stock farmer; B. H. Dessler, Juno ranchman; Herman Schafer, Brackettville, laundry employee; Harold Davis, Crystal City laborer; and Chester N. Neely, Sabinal mechanic."

The jury was chosen from some thirty residents of the Western District, most of them ranchers and farmers of this area, some representing various businesses. After preliminary addresses to the jury by the attorneys, the lawyer for the plaintiff presented as exhibits the articles published in *Hygeia* for January and February 1938.

TESTIMONY OF EFFIE KELLEY

The first witness, Miss Effie Kelley, stated that she was a newsdealer in the city of Del Rio and that the periodical had been circulated in the town.

TESTIMONY OF A. C. PETERMEYER

The second witness was A. C. Petermeyer, who stated that since April 15, 1938, he had resided in Little Rock, Ark., and before that time, from October 1933 to April 1938, in Del Rio, Texas. He stated that he was a physician and surgeon, licensed in May 1917 in Missouri; by reciprocity in 1918 in Kansas, where he became associated with the Brinkley Hospital in Milford in October 1933. He moved with the Brinkley group to Del Rio, where he remained until removal to Little Rock in 1938. He obtained his license in Texas in 1929. After stating that he had observed the work of Dr. Brinkley during his association, the evidence proceeded as follows:

Q.—Now, tell us, Dr. Petermeyer, please sir, what specialty, if any, Dr. Brinkley engaged in while here in Del Rio? *A.*—His specialty was dealing more with the infections and hypertrophy of the prostate gland, in conjunction, of course, with the treatment and surgery of other urinological conditions. By that I mean urinological—I mean the urinary organs, the kidneys, the bladder and urethra.

Q.—And was Dr. Brinkley or not during all of that time engaged in the active practice as a physician and surgeon? *A.*—He was.

Q.—Was he or not during that time himself performing operations on patients? *A.*—The majority of them.

Q.—For prostatic trouble? *A.*—Yes.

Q.—And cases of that nature? *A.*—Dr. Brinkley was performing practically all of the operations.

Q.—Now, tell us, please, Doctor, what hospitals he has in Little Rock, Arkansas, please, sir? *A.*—Dr. Brinkley has a hospital at Twentieth and Schiller Avenue in the city of Little Rock, and a second hospital on the Arch Street Pike, about sixteen miles from the city of Little Rock.

Q.—Tell us what the nature of the practice in those hospitals is and what they are operated for, particularly for what purpose? *A.*—In the two hospitals there are these departments, the urinological department, which treats, examines and treats and operates conditions of the urethra, urinary tract, kidneys, bladder, prostate gland, testicles; and the rectal department, where all pathological or disease conditions of the rectum and colon are treated. We have a hernia department where we specialize in the injection treatment of hernia. Those are the three departments that we have.

Q.—Now, how many hospitals—I mean is that all in one hospital? *A.*—The majority of that work is done at the hospital at Nineteenth and—or Twentieth and Schiller. The hospital in the country is used more for our patients who have had work to come back for free examinations and check-ups and to receive additional treatment should any of them be in need of it, but the hospital on Schiller sometimes is filled to capacity so that new patients arriving at that hospital are sometimes taken care of at the hospital in the country.

Q.—Tell us what personnel there is at the hospital there, Doctor, with reference to doctors and help in the way of nurses. *A.*—At the city hospital Dr. Brinkley and Dr. Osburn are in charge of all the urinological treatments and surgery. Dr. H. J. Hilburn specializes in diseases of the rectum; also the treatment for varicose veins and hernia. Dr. Davis is in charge of the physical examinations, Dr. J. H. Davis makes all of the physical examinations of the new patients coming to the town hospital. Dr. Chandler is in charge of the x-ray department and chemical laboratory. Mr. Kirschberg is the laboratory technician. There are two or three more whose names I am not familiar with who are working in the laboratory under Mr. Kirschberg. Mr. Kirschberg is a licensed laboratory technician. At the country hospital Dr. Parnell is in charge of the patients who arrive there for their rechecks and treatment. Dr. Hilburn reports there every afternoon to treat rectal and hernia cases. When the city hospital is filled to capacity and new patients are then taken to the country hospital where they are operated by Dr. Osburn. Miss Vira Wederbrook is superintendent of the town hospital. She is the surgical nurse and assistant to Dr. Brinkley and Dr. Osburn. We have a staff of graduate nurses, the names of whom I am not able to give you.

Q.—Yes, sir. *A.*—But there are twelve or more graduate nurses.

Q.—Now, Dr. Petermeyer, can you tell us who of those doctors were with Dr. Brinkley here in the hospital here? *A.*—Dr. J. H. Davis, who is examining physician at the town hospital in Little Rock, was also examining physician at the hospital in Del Dio; Dr. Chandler, who is in charge of the x-ray department in Little Rock was also in charge of the x-ray department while the hospital was located in Del Rio; Mr. Kirschberg, a licensed technician, was also in Del Rio.

Q.—Now, Doctor, can you tell us, please, sir, what the extent or volume of the practice of Dr. Brinkley was here in Del Rio? *A.*—You mean the number of patients?

Q.—Yes, sir. Just give us an idea of the volume of his—and extent of his practice and where they came from while he had his hospital here? *A.*—While the hospital was located in Del Rio, Texas, patients came to the Brinkley Hospital from every state, practically every state, practically every province in Canada, Alaska, Nova Scotia and Central America.

Q.—Well, were the— *A.*—The number of patients during that time from October 15, 1933, to January 1, 1938, would be somewhere in the neighborhood of fifteen thousand.

Q.—Now, for what length of time was that fifteen thousand, over what period? *A.*—From 1933, about October, to January 1, 1938.

Q.—Now, do you know whether or not you had many patients from this general locality in and around Del Rio? *A.*—Yes, we had more patients from the state of Texas than any other locality.

Q.—A great many more from Texas than other places? *A.*—Many more.

Q.—And a great—did you or not have a great many patients from the general region around Del Rio, in and around Del Rio? *A.*—Yes, we had a large number of patients from Del Rio and Val Verde County and surrounding counties.

Q.—Now, Dr. Brinkley has a license to practice in Texas. *A.*—Yes.

Mr. Brown:—I don't think this gentleman would know about that.

THE COURT:—The license would be the best evidence.

Mr. Morris Jr.:—You admitted that in your answer. Do you make any question about his having his license to practice?

Mr. Brown:—We just have the formal objection, if the court please, that this gentlemen wouldn't be able to testify to that.

THE COURT:—If there is no issue about it why waste time on it? Is it admitted he is licensed to practice in Texas? We have plenty of issues in the case without wasting time. Is there any admission on that?

Mr. Brown:—No. I just didn't want this gentleman to get out of the general field.

THE COURT:—I think we have lost time by the objection. Go ahead.

Q.—And do you or not know that during all that time he was engaged in the active practice of his profession? *A.*—He was.

Q.—And is he yet engaged in the practice as a physician and surgeon? *A.*—He is.

Q.—Did you know anything about the article which was published in *Hygeia*, the article herein sued on, at the time it came out, about that time? *A.*—Yes, I read it.

Q.—And did you or not have any occasion to discuss the matter or observed Dr. Brinkley with reference to the article? *A.*—Yes.

Q.—And what affect it had on him? *A.*—Yes, sir.

Q.—Just tell the jury, please, sir. *A.*—Well, the—

Mr. Brown:—Your honor, I don't remember if there is any issue as to what effect it might have had on him personally.

THE COURT:—I think he claims he suffered mental anguish.

Mr. Brown:—All right.

Q.—Go ahead, tell what you observed in that connection, just tell the jury. *A.*—There was a great deal of conversation on the street by the people of Del Rio. A large number of copies were requested from our news stands so that people could read it. The article humiliated Dr. Brinkley in the presence of his friends and acquaintances in Del Rio, as well as with the members of his profession.

Q.—Did it or not appear then to bother and distress him a great deal? *A.*—It did; Dr. Brinkley was rather reluctant to appear in public after that article was published about him. Naturally it would make any one feel reluctant to appear in public after that.

CROSS EXAMINATION

Questions by Mr. Brown:

Q.—Dr. Petermeyer, what college is it, please, that you graduated from? *A.*—The American School of Osteopathy and Surgery, at Kirksville, Mo.

Q.—Did they specialize there principally in bone work? *A.*—No; the curriculum at Kirksville is practically the same as any class A school; the subjects taught and textbooks used are standard ones.

Q.—But it is known as a college of osteopathy, is it not? *A.*—It is.

Q.—Did you perform the surgery after you came to Del Rio, in Dr. Brinkley's hospital? *A.*—I was doing the surgery, part of it, when I came, but the majority of it was done during 1936 and 1937.

Q.—That is after you had been here some time? *A.*—Yes.

Q.—Did you ever do that operation where they take a part of a goat and put it in a man? *A.*—No.

Q.—Do you operate in the hospital up in Arkansas? *A.*—No.

Q.—What is the principal type of operation that they do when a man has a complaint, as far as his prostate glands are concerned? How do you operate for that ordinarily? *A.*—Do you want a complete description of the operation, how it is performed?

Q.—Yes, if you please. *A.*—After the patient has been accepted for treatment and is in need of treatment to the prostate gland, and all of the preoperative treatment has been performed, and the patient has been prepared properly to receive an operation—I will just give you the technic of the surgeon in the operating room. That is what you want?

Q.—In words we can understand, if you please. *A.*—The scrotum is anesthetized with apothesine.

Q.—With what? *A.*—Apothesine, a local anesthetic. The testicle is picked up in the left hand with the index finger of the right hand; the head of the epididymis is an appendage of the testicle; and an incision is made through the skin, through the dartos, through the fascia, through the cremasteric muscle—

Mr. Morriss:—Tell us what those are.

Q.—That is just cutting down to get to the testicle? *A.*—Yes. An incision is made through the scrotum down to the testicle. The testicle is lifted up into the incision so that the epididymis is available.

Q.—Tell us just in language that we may understand better. What is the epididymis? *A.*—It is a collection, you might say, of tubules attached to the side of the testicle. It has two parts.

Q.—Kind of like an appendage? *A.*—You might consider it something like that. It consists of a large area known as the globus major and a tail of it known as the globus minor. From the globus minor we have an extenuation of a tube known as the vas deferens.

Q.—That runs still on up? *A.*—That runs on up to the seminal vesicles. After the testicle is brought up into the incision so that the—this appendage, the epididymis, can be thoroughly examined, the ducts which lead from the testicle to make up the epididymis are inspected and examined with the examining finger.

Q.—Now, excuse me. I am not very familiar with it, of course. Is there a little space, a little distance between the main bulk of the testicle and where the addition or appendage is? Is there a little space there? *A.*—Yes, sir, slightly.

Q.—About how much is that, ordinarily, just in a general way, those little tubes, about how long would they be ordinarily? *A.*—Which tubes are you speaking of?

Q.—The ones reaching from the testicle, that you mentioned, up to the epididymis? *A.*—They are very short, perhaps 1 centimeter in length after they leave the testicle to where they converge in the epididymis. In fact, the epididymis is so closely attached to the testicle, it is closely attached to the testicle with tissue, but you can feel with your finger the space between the epididymis and the testicle.

Q.—Now, what do you do then in respect—I interrupted you there. What do you do with respect to examining those little tubes? *A.*—We examine them with the fingers to feel for the presence of small nodular areas, which usually mean infection.

Q.—What do you call those little tubes, technically? *A.*—The vasa efferentia.

Q —Now, is there another word they use for it, some kind of efferent tubes? A —It is the same thing

Q —Efferent tubes? A —Yes

Q —Now, how many of those, ordinarily, in each testicle? A —Fifteen to twenty

Q —Well, after you have then examined and found which one is diseased, if any, and the condition, what do you do then in continuation of the operation? A —They are ligated

Q —What does that mean, please? A —Tied off

Q —Well, is the number in each testicle in every person always the same? A —They may vary

Q —Do they vary in different people in number, I mean? A —Yes

Q —Well, how many do you tie off ordinarily? A —Sometimes all of them and sometimes half of them and sometimes none

Q —I say ordinarily, an ordinary operation? A —The ordinary operation, seven or eight of them are ligated or tied off

Q —Substantially half of them? A —Yes

Q —Does that tied off mean—does that mean that no fluid or anything can go through that one any more? A —Yes sir

Q —It stops it? A —Yes, sir

Q —Well, if you stop all of them in each testicle, what result would that have? A —Well, on what?

Q —I mean on the man's sexual powers For instance, what would be the effect of it? A —Sometimes it increases it

Q —To tie them all off? A —Yes sir, all of them

Q —All of the tubes? A —Yes, sir

Q —I mean, now, as to sterility? A —It would produce sterility, but at the same time increase his sexual vitality

Q —What is the difference between sterility and impotency? A —Sterility means that the individual is not able to produce a heavy male sperm, which when it comes in contact with the female ovum will cause a direct cell formation

Q —In other words, he can't have any more children? A —That is right

Q —But that condition can exist and at the same time he would have the ordinary sexual power except for the production of children? A —He could have

Q —But if you cut them all off on both testicles that would produce sterility? A —It would

Q —And in the ordinary operation you cut off about half of them? A —Yes

Q —Of course, that varies in the different patients, I imagine? A —Yes

Q —Now, what else do you do now in addition to cutting off some or all of these little tubes that run between the main part of the testicle and the appendage there? A —The artery running along the vas deferens is also ligated, tied off

Q —That is the blood vessel that runs along the tube that goes on up from the testicle, that goes on up? A —Yes, sir The vas deferens is picked up and injected with about 5, 3 to 5 cubic centimeters of a 2 per cent mercurochrome solution This solution is injected through the vas deferens and if the tube is open and functioning the solution will pass on into the seminal vesicles

Q —What is that last you mentioned? A —Seminal vesicles?

Q —Yes A —Small vesicles are located between the rectum and bladder, just above the prostate, and is a sort of reservoir or storehouse for seminal fluid As it passes upward from the testicles this solution reaches the seminal vesicles, if they are distended with it considerably, and out through the ejaculatory ducts These two little tubes leading from the seminal vesicles lead to the prostate In fact, they go through the posterior aspect of the prostate gland, emerging on the floor of the prostate The solution usually appears the next time the patient voids At least a part of it does It does away with the catheterization of the ejaculatory ducts, which are often blocked with infection If the solution will not pass into the seminal vesicles or if we find the vas deferens is blocked and it presents plenty of evidence of infection we may remove a portion of it

Q —Of what is that? A —Of the vas deferens

Q —Why? A —Because it is like any other focal infection, like the appendix or tonsils or any other organ, if it can no longer function it becomes a menace to the future health of the individual

Q —And you cut out a portion of them? A —Yes, sir

Q —About how long in length is that, ordinarily? A —It may be from an inch to 4 or 5 inches in length

Q —Does that also produce sterility A —A patient is already sterile, if the mercurochrome will not pass through the patient is sterile

Q.—Is that all of the ordinary and usual operation that you do for the condition? Now, what effect—excuse me—what effect does that operation have on an enlarged or diseased prostate gland? A —Research workers and scientists who have been working along the lines of the glandular system have fairly well agreed on the fact that there are two secretions from the testicles The one secretion, or excretion—

Q —Excuse me please I meant to say that as far as the enlarged prostate is concerned, the operation you mentioned there whether that will eventually cause the prostate to become smaller, be relieved as far as the passing of urine is concerned? A —That is what I was coming to I was only explaining it a little more in detail

Q —Yes, sir Now, then, in reference to—

Mr Morriss Jr —Let him answer the question

Mr Brown —You can ask him

Q —If the prostate is enlarged so that it blocks the passage of the urethra do you ever cut a portion of it out? A —If the prostate is enlarged enough to produce over 4 ounces of residual urine—by that I mean the gland is enlarged so much that it will not permit the bladder to empty.

Q —Then what do you do? A —A transurethral resection is necessary

Q —What is that? A —That is the removing of the obstructing portion of the prostate

Q —Do you have to make an incision? A —No, the instrument is passed through the urethra and the operation is performed through the sheath of the instrument you use

Q —Now, does Dr Brinkley's hospital ordinarily charge for—what does it ordinarily charge for that operation? A —Transurethral resection? We usually charge $250

Q —And for this operation you described first, about the testicle? A —From $275 up

Q —Does he sometimes give a guaranty after one of these operations? A —We give future service, yes sir, and we guarantee to the patient that if the operations that he has received does not reduce the growth of the prostate gland so he can empty his bladder properly he is privileged to return *and have a transurethral* resection at no additional expense

Q —Does that cost $750? A —Yes sir That also includes his hospitalization and his medications and dressings, anesthetic and operating room fee

Q —You mentioned a while ago a class A medical school What do you mean by that, please? A —The medical schools are classified, I think A and B, and an A school having a higher rating than a B school

Q —Do you know who it is that classifies the different medical schools throughout the country? A —No

Q —Don't you know, Doctor, that is—that it is a fact that they are classified in that classification as accepted by the American Medical Association? A —I presume so

Q —That is your understanding of it, is it not? A —Yes

Q —Now, up there at the hospital there, as I understand it you are now no longer serving as a doctor, but you are the business manager, are you? A —Yes

Q —Do you know of any other recognized doctors in the United States that use the technic of operation that you have here described? A —Yes sir

Q —Who are they, please? A —I do not have the consent to divulge their names, but I can give you one whose article has appeared in literature published by the institution

Q —By which institution do you mean? A —From the Crile Clinic in Cleveland, Ohio

Q —That is the institution that published what, what was it? A —The institution published this article, the article was written by Dr. Lower, who is in charge of the George Crile Clinic

Q —At what place? A —Cleveland, Ohio

Q —You don't want to name any others that do this same operation that you all do? A —Not having their permission to divulge their names I wouldn't care to

Q —All right, sir Now, as I understood it, you said you operated on about 15,000 people here at Del Rio? A —No, that number of patients came to our hospital

Q —Oh, I see Well, of that number, how many were operated on, do you remember? A —No, I do not

Q —Do you know what the average charge for the operations was while they were here in Del Rio? A —The average charge would be including their hospitalization and operating room fee and anesthetic and examination. Their entire expense would probably average around $400

Q —Did Dr Brinkley or any one in his hospital after they got here to Del Rio, did they ever use the goat gland? A —No

Q —Transplanting the goat gland in a human? A —No

Q —By the time they got here they had quit that, had they? A —There was none of that done here

Q —Are you doing any of that up in Arkansas? A —No

Q —Did you ever do any of that yourself in Kansas when you were there at Milford with the doctor? A —No

Q —Did you ever see any of it done while you were there? A —No

Q —The man that wrote that article up there for the Crile Clinic saying he had done this same operation, did you mean cutting out a portion of the prostate gland or the operation you first described, that is where you tied away the little tubes? A —A ligature operation, yes, sir

Q —That is the one he described in that article, is it? A —Yes, sir

Q —Do you know whether or not that doctor also put the mercurochrome in the tube also, like you do? A —I don't recall

Q —Do you get more patients with this trouble of the prostate from the cold states or warm states, or is there any difference? A —There is a difference, because cold weather affects urinary troubles more than warm weather, and we have a great many patients, of course, from both regions warm and cold, but cold weather does affect and aggravate the symptoms of the prostate and bladder

Q —Also do you get more people from the north of you or south of you, from Little Rock? A —I don't believe there is very much difference

Q —Do you know about how many patients they operate on there now in Little Rock since you have been there, how many they operate per week for this ordinary operation? A —During the past two months I expect the average would be about fifty, between forty and fifty a week

REDIRECT EXAMINATION

Questions by Mr Morriss Jr

Q —You spoke of the operation when all of the ducts are ligated as producing sterility Do you or not ever perform any operation which might produce or continue a sterile condition in a man without first fully explaining that situation to him and obtaining his consent? A —No we do not

Q —Is that the universal practice in that respect? A —It is

Q —Well, now, is that usual in the case of very old men? A —Altogether

Q —Now, Doctor, you also told us that a charge of $750 was made which covers the operation and hospitalization Does it or not also include the examination which is made? A —Yes it does

The witness then outlined what was said to be the regular physical examination of patients coming to the Brinkley Hospital, beginning with the top of the head and through the body, as is usual in complete physical examinations, describing also the basal metabolic test, the use of the cystoscope, electrocardiograph, and the x-rays. He also described in detail the equipment of the institution, proceeding then as follows

Q —Now, then, Dr Petermeyer, I want to ask you this question, please sir Counsel asked you whether any other type of operation was performed and you spoke of the transurethral resection A —Yes, sir

Q —Will you explain to the jury what that consists of and how that operation is done?

THE COURT —I think he explained that *on* cross examination

Mr Morriss Jr —I didn't understand it so

THE COURT —Counsel asked him what it was and he told him what the operation was Now, you have had this witness on the stand for a long time If you are going to back track and repeat we will never get through

Mr Morriss Jr —I wasn't back tracking—

THE COURT —I am not arguing with you, Counsel That is the ruling of the Court.

Mr Morriss Jr —Yes, sir Note the exception

Q —How many different types of operations would you say are done with reference to the prostate, then? A —Aside from our routine procedure operation we *do that and also* the suprapubic operations That is opening into the bladder above the pubic bone, openings there are *made* to remove large stones and growths We also remove stones by a crushing instru-

ment which is introduced through the urethra, through the urinary canal, providing the stone is not too large. The instrument will remove a stone about 3½ centimeters; that would be about, well, say about an inch or an inch and a half in diameter. The instrument will pick up a stone that size and crush it, and by crushing each fragment separately it can be washed out through a tube or sheath.

Q.—Are there any other operations that are performed, Doctor? *A.*—Operations on the testicle, scrotum, penis, kidney, bladder.

Q.—Now, in my questions of you I have intended these questions to apply to the time that this article was published, and let me ask you whether or not your answers to these questions, whether the same answer is applicable to the time which the article was published, as to the various operations and examinations given and treatment? *A.*—It is.

Q.—And the technic pursued? *A.*—The same.

Q.—Now, how long, Dr. Petermeyer, have you been observing Dr. Brinkley in the performance of prostate operations? *A.*—Since 1933.

Q.—And have you or not assisted him during that time with operations? *A.*—Prior to the time he located his hospital in Little Rock?

Q.—Yes, sir, that is what I say, while he was here in Del Rio? *A.*—Yes, sir.

Q.—You assisted him with the operations, did you, Doctor? *A.*—Yes, sir.

Q.—And did you or not in many other instances in which you did not assist, observe the operations? *A.*—Yes, sir.

Q.—And can you tell us how many operations you have seen Dr. Brinkley perform for prostate trouble? Just give us your best estimate. *A.*—Oh, several thousand.

Q.—Now, Doctor, have any of these patients who have come to Dr. Brinkley originally and received any of these operations, have they returned during the time you have been with the hospital? *A.*—They have.

Q.—And have you or not had an occasion to examine and observe them prior to their first operation by Dr. Brinkley? *A.*—Yes, sir.

Q.—And have you or not had occasion to observe and examine them subsequent to the operation? *A.*—Yes, sir.

Q.—Well, now, just tell the jury as best you can what the practice with reference to the patients is with reference to returning, and approximately how many you would say that you have had the occasion to observe, and how long after they had been to Dr. Brinkley was it that they would come back? *A.*—From 1933, until January of 1938, I had occasion to examine a large number of patients who came to the hospital, to give them the preoperative treatment and either see them operated by Dr. Brinkley or operate them myself, give them the postoperative treatment and check them out or dismiss them from the hospital at the end of their hospitalization time.

THE COURT:—That wasn't the question he asked you, Doctor. He asked you about those that came back.

A.—Oh, yes. Our patients are privileged to return for rechecks, for examination. We want them to, and if they don't return in a certain length of time we frequently write them and ask them why they haven't come back for their examination or check-up. I would say that 5 per cent, about 5 per cent of the patients return for additional work.

Q.—Now, then, after what length of time have they been out, ordinarily, just tell us what varying lengths of time. *A.*—The time varies from six months to several years.

Q.—Now, then, Doctor, tell us with reference to those patients which you have had an opportunity to examine and observe prior to the time of their operation and subsequent to the time of their operation, what you have found with reference to beneficial effects of the operation given? *A.*—I would say that 80 to 95 per cent of the patients respond favorably to the treatment.

Q.—Well, now, tell us what you mean by responding favorably, what effect it has, what physical effect? *A.*—Those who have received our routine operation and treatment for infection or enlargement of the prostate gland?

Q.—Well, I am talking about the gland, what effect you have observed in the way of improvement or benefits received? *A.*—The benefit has been general. They have been not only able to empty their bladders better and be relieved of their urinary symptoms, but they have felt better and in a general way have gained weight and their rest is improved and they sleep better. Many of those who were not able to work at all are able to go home and within a reasonable length of time go back to their job.

Q.—Do you mean by that, then, Doctor, that the operation was successful in those percentages of cases that you have told us? *A.*—Very.

The witness then described the method by which records are kept in the hospital, after which the evidence proceeded.

Q.—Now, Doctor, please explain to us—counsel asked you about it, about the guaranty. Just what that consists of, what it entitled the patient to, explain that to us? *A.*—The guaranty, or lifetime future service, entitles the patient to return at any time regardless of time for free examination and check-up. Should we find that he is in need of further treatment we offer it to him at no additional expense. If he needs a transurethral resection, that is performed without any additional expense other than his board and room in the hospital, but he never pays any more for treatment or surgery pertaining to the type of work that he came for.

Q.—Then in these cases, Doctor, is it not true that when they first come you make the complete examination and then the operation or treatment is given and then is the patient also requested to return within six months or a year for an additional check-up and to return regularly? *A.*—No, he is not. It is not compulsory, he does not have to return, but we ask him to and request that he does.

Q.—Yes, sir, that is what I say, that he is requested to return for additional examination and check-up to see how his general physical condition is getting along, is that correct? *A.*—Yes, sir.

Q.—And that additional examination and check-up and any further treatment which may develop to be necessary of the prostate is all administered without additional charge, is that right? *A.*—That is right.

Q.—Doctor, about how long do the patients remain in the hospital after the operation? *A.*—In uncomplicated cases they usually remain about seven days.

Q.—And how long are they there before the operation? *A.*—That depends somewhat on the time necessary to make the examination and depends on the condition of the patient, whether or not he is an operative risk at that time. Occasionally we have to keep a patient several weeks, or into the second week or several weeks, before he is operated, and occasionally at that length of time we send him home without any service because we feel he would be a poor operative risk.

Q.—You mean his physical condition is determined by you as such that you feel you could not help him or benefit him with an operation? *A.*—We feel we could not help him and he might die as a result of the operation from shock or from being in a debilitated condition.

Q.—Because of his debilitated condition? *A.*—That is right.

Q.—In those cases do you make a charge to the patient? *A.*—We make a charge of $50 for the examination plus $35 a week in the hospital.

Q.—Is that all of the charge that is made to them? *A.*—We charge sometimes for medications and sometimes we charge just for the examination and their hospitalization.

Q.—Now, with reference to the injections of the mercurochrome solution, Doctor, in the vessels, as you have described it, just tell the jury where that is injected and what is its course?

THE COURT:—No, he has described that, counsel, once.

Mr. Morriss Jr.:—I want to know the purpose of it.

THE COURT:—If you are going to go over the testimony of every witness like you have on this doctor we would be here too long. I want you to bring this examination to a close. You have brought him way beyond the realm of redirect examination.

Mr. Morriss Jr.:—Well, it is—

THE COURT:—You will have to comply with the Court's rule.

Mr. Morriss Jr.:—I wasn't going to ask that question, I was going to ask in connection with what was the purpose.

THE COURT:—He has told why he did it.

Mr. Morriss Jr.:—Has he explained that?

THE COURT:—Yes, sir.

Mr. Morriss Jr.:—Note the exception.

THE COURT:—Exactly why they did it, what they did and why they did it. It is going over the same thing twice.

Q.—Is the system of examination and treatment of the patient after you have—as you have given it to us, Doctor, is that the system which was inaugurated and required by Dr. Brinkley in the treatment of prostatic troubles? *A.*—Yes, sir.

RE-CROSS EXAMINATION

Questions by Mr. Brown:

Q.—Doctor, at any hospital they give a patient a complete examination before they operate on him, don't they, and they take his history? *A.*—I think they do.

Q.—And they make a chart of all the patient tells them and of the conditions they have found, don't they? *A.*—They do.

Q.—Do you know what this formula 1020 has in it? That is Dr. Brinkley's formula, isn't it? *A.*—Yes, sir.

Q.—Do you know what he has in it? *A.*—Yes, sir.

Q.—What is that? *A.*—I haven't his permission to answer that.

Mr. Brown:—We would like to know.

THE COURT:—You will have to answer the questions, Mr. Witness.

Q.—How much do you charge for that No. 1020?

THE COURT:—Wait a minute, they have some objection.

Q.—How much charge is made for that prescription 1020? *A.*—Of course, a treatment with that intravenous medication we charge $100.

Q.—Is that the one you have given the patient to take home and have it put in him by his home doctor when he gets home? *A.*—No.

Q.—Postoperative treatment? *A.*—No, we give that to him at the hospital.

Q.—The doctor at home doesn't use 1020? *A.*—Only if he is a recheck patient and does not have time to remain longer.

Q.—But anyway you charge $100 for prescription 1020? *A.*—Not for that if he takes it home, if he takes it home there is no charge.

Q.—If it is given in the hospital there is a charge of $100? *A.*—Yes, sir.

Q.—What has it got in it?

Mr. Morriss Sr.:—Of course, this witness says he is an employee of that hospital and this is a proprietary—

THE COURT:—I know, but if he knows it. He is here testifying on the stand. He will have to answer the question.

Mr. Morriss Sr.:—It is privileged.

THE COURT:—There is nothing privileged about it.

Mr. Morriss Sr.:—Would it not be privileged in a sense in that it is a matter that belongs to his employer and—

THE COURT:—No, I don't think so.

Mr. Morriss Sr.:—In other words, a trade secret.

THE COURT:—I don't see any secret. He said he gives it to the patient to take home, and chemists could analyze it.

Mr. Morriss Sr.:—Note the exception.

THE COURT:—Answer the question if you know.

A.—The chief element in it is hydrochloric acid.

Q.—What per cent of it is hydrochloric acid? *A.*—I don't know.

Q.—Very small, is it not? *A.*—No, sir.

Q.—Do you have any idea of the percentage? *A.*—Perhaps one to one thousand.

Q.—One to one thousand. In other words, one thousand of what, water? *A.*—Yes.

Q.—One thousand of water and one of hydrochloric acid? *A.*—Yes.

Q.—Is that all it has in it? *A.*—No.

Q.—What else has it got in it? *A.*—Mercury.

Q.—How much mercury? *A.*—I don't know the percentage.

Q.—What else has it in it? *A.*—It has methylene.

THE COURT:—Are you talking about now or at the time?

Mr. Brown:—At the time, if you please.

A.—Methylene.

Mr. Brown:—At the time or before?

THE COURT:—You had better make that clear because the evidence shows Dr. Brinkley is running a place up in Arkansas, and we are only interested in what happened down here.

Mr. Brown:—This article was in February of last year, and I am talking about either at that time or a reasonable time before that.

THE COURT:—All right.

Q.—What else has it in it, please? What else had it in it, please? *A.*—I believe that is about all.

Q.—How much did you have to pay, wholesale, for that stuff you put in 1020? *A.*—I don't know.

Q.—Now, do you know what was in these other prescriptions that he prescribed over the radio, prescriptions No. 50 and 60 and those other prescriptions he would talk about over the radio and the person would go to the drug store and get the prescriptions by number so and so? Do you know what is in those prescriptions? *A.*—No, sir.

Mr. Morriss Jr.:—We want to object to that question as assuming something not proved. It is a duplicitous question also.

THE COURT:—Yes, it is not in line with anything he asked on redirect examination. I don't think it is proper re-cross examination of any matter.

Mr. Brown:—Yes, sir.

Q.—Do you know what gives that 1020 the blue color to it? *A.*—The methylene, I believe.

Q.—Now, what pathologist is it there at your hospital, or was it at the time of this article and before, what pathologist was it that made this investigation of the tissues and so forth? *A.*—Mr. Kirshberger.

Q.—Mr. Kirshberger? *A.*—Yes.

Q.—He is a doctor? *A.*—A licensed technician.

Q.—Who licensed him, do you know? *A.*—Oh, no.

Q.—Do you know of anybody—is there such a thing as a licensed laboratory technician? *A.*—Well, these technicians who graduate from some of these standard laboratories.

Q.—You don't know who licenses them? Do they get licenses from the state, or whom? *A.*—I don't know.

Q.—Now, is this Dr. Brinkley's hospital, or was it at the time here and before, was his hospital approved by the American Hospital Association?

Mr. Morriss Jr.:—We object to that as being irrelevant and immaterial and having no bearing upon the question.

THE COURT:—Overrule the objection.

Mr. Morriss Jr.:—And as being hearsay in its nature, and without any probative force and prejudicial to the rights of the plaintiff.

THE COURT:—If the witness knows I think it is legitimate examination.

A.—I don't know.

Q.—Was it approved by the American College of Surgeons?

Mr. Morriss Jr.:—The same objection.

THE COURT:—What is the witness's answer?

A.—I don't know.

THE COURT:—He says he doesn't know.

Q.—As I understand it, Doctor, you operated while the hospital was here in Texas, did you? *A.*—Yes, sir.

Q.—And was Dr. Osburn here at the hospital at that time? *A.*—No, sir.

Q.—Did he ever work here at the hospital, Dr. Osburn? *A.*—In the business office.

Q.—But he didn't operate, did he? *A.*—No.

Q.—But he was the business manager in Texas and you operated, is that right? *A.*—Yes, sir.

Q.—Then when you moved to Arkansas you changed it there, he operates there in Arkansas and you are the business manager, is that right? *A.*—Dr. Brinkley and Dr. Osburn.

Mr. Morriss Jr.:—We object to that as being immaterial and irrelevant, anything that may be done after the article in question was published.

THE COURT:—I don't know, it goes to the qualifications of these parties.

A.—Dr. Brinkley—

THE COURT:—Just a moment. It goes to the qualifications of these parties, to develop their qualifications. Overrule the objection.

Mr. Morriss Jr.:—Note the exception.

A.—Dr. Brinkley and Dr. Osburn.

Q.—Now operate in Arkansas? *A.*—In Little Rock.

Q.—And you are the business manager? *A.*—Yes, sir.

Q.—Do you make the arrangements to get the money out of the folks before you do the work on them? *A.*—No, sir.

Q.—You do it for nothing, without getting any money? *A.*—The patient pays the business manager of the hospital. I am at the business office and have nothing to do with the collection of fees.

EXHIBITS

The attorney for the plaintiff then presented in evidence as exhibit the issue of *Hygeia* for January 1938 containing the first portion of the article entitled "Modern Medical Charlatans," and particularly the portion which read: "In a few spots over the United States, around 1925 to 1930, local stations continued to pour forth filth and falsehood. In the obscure Kansas village of Milford, a blatant quack, one John R. Brinkley, whose professional record reeks with charlatanism of the crudest type, had for some years been demonstrating the commercial possibilities of goat-gland grafting for alleged sexual rejuvenation."

TESTIMONY OF LOWELL BROWN

The next testimony was that of Lowell Brown. He testified that he was tutor for Dr. Brinkley's son and that he made a trip with them to Europe in 1937. He described the conduct of Dr. and Mrs. Brinkley on the boat, stating that they associated freely with the other passengers. He stated also that Dr. Fishbein was a passenger on the same boat. The evidence then proceeded:

Q.—Well, did any of your party associate with the people on the boat, with his people or any of them? *A.*—Yes, I think Dr. Brinkley's son and Dr. Fishbein's boy played together for two or three days until they knew whose sons they were. In fact, I visited with Dr. Fishbein's daughter and played ping-pong with her a few times, and we drove a golf ball into a blanket hanging on the ship there, and along about the second or third day I visited with her I casually remarked to her if she knew who my boss was and she said no, and I told her and she was interested in asking what kind of man Dr. Brinkley was.

THE COURT:—Counsel, is this competent.

Mr. Morriss Sr.:—I don't know where he is leading, your honor. I don't know whether it is or not, but it may be.

THE COURT:—I know, but it seems to be some narration of an episode between him and a girl.

The Witness:—Well, it is—

THE COURT:—Just a moment, Mr. Witness, you be quiet until the Court has colloquy with counsel and confine yourself to answering questions. What do you say about it, counsel?

Mr. Morriss Sr.:—I am sure that it would be of no moment unless something came of it. I will ask him this:

Q.—Did that association continue on the trip throughout, or was it terminated, or what? *A.*—She terminated the conversation rather abruptly. I think we spoke a time or two after that but never associated any more after that.

Q.—Was it or not terminated by you, on your account, or was it terminated because of her?

THE COURT:—Counsel, I don't think that is binding on Dr. Fishbein and I don't think it is relevant unless you can show something with regard to the article itself.

Mr. Morriss Sr.:—This was before the article, your honor, this is some time before.

THE COURT:—I know that, but the charge in the article was on the ship they didn't associate with other people. Now you are trying to prove what this tutor here did.

Q.—Now, then, what about Doctor's—was the party composed of the doctor and his wife and son and you? *A.*—Yes, that is correct.

Q.—You speak of yourself, were you with his son? *A.*—Yes, sir.

Q.—His little boy? *A.*—Yes.

Q.—How old is the doctor's boy? *A.*—Eleven years.

Q.—Well, now, what about Dr. and Mrs. Brinkley on that trip back, did they or not refuse to associate with anybody, or anything of that kind? *A.*—Just the usual thing, just as I tell you. I could have told you with the other questioning. There was a picture taken, a group picture at the dinner table one evening on the *Queen Mary* going over. I don't believe any picture was taken coming back. I don't know of anything extraordinary about any of our behaviors in any way.

Q.—What do you mean, group picture? *A.*—Dr. and Mrs. Brinkley and Johnny Boy and myself, and I have the picture at home, and I am sure they do.

Q.—Were they in company with others? *A.*—Yes, sir, people all around them. Of course, the picture was taken by flashlight of us, of the family, and I think the picture will show in the background other tables besides ours. It was in the dining room.

He then stated that Dr. Brinkley was a delegate to the Rotary convention on this trip.

The cross examination follows:

CROSS EXAMINATION

Questions by Mr. Brown:

Q.—Have you ever been with him on any of his yachts? *A.*—Yes, sir.

Q.—What was the name of the yacht that you were with *him* on? *A.*—Well, it was called *Dr. Brinkley No. 2.*

Q.—*Dr. Brinkley No. 2?* *A.*—Yes, sir.

Q.—And where did you go on that occasion? *A.*—Well, my first yacht trip was up and down the New England coast. I got on the yacht at Port Washington, Long Island.

Q.—Did you ever see yacht No. 1, Dr. Brinkley's yacht No. 1? *A.*—Yes, sir.

Q.—Have you seen Brinkley No. 3? Is there a No. 3? *A.*—I think it is also called No. 2, but I have been aboard of it.

Q.—In other words, he has been the possessor of three fine yachts, hasn't he?

Mr. Morriss Jr.:—We object to that, it is irrelevant and immaterial and a conclusion and opinion of the witness.

THE COURT:—If you strike the word fine out the question will not be subject to objection.

Mr. Brown:—Yes, sir. What they declared on here is that he has been the possessor of three fine yachts, hasn't he, Mr. Witness?

THE COURT:—They objected to that as calling for a conclusion, whether or not he knows what a fine yacht is. Why don't you confine it to "three"?

Q.—He has owned three yachts, hasn't he? *A.*—Yes, sir.

Mr. Morriss Jr.:—We would make the further objection, your honor; for instance, they may have made some statements in the article which were true. That in no manner, or the proof of the truth of those in no manner relieves or tends to relieve the other.

THE COURT: I know, but they can prove all of their case at one time. Of course, it may be that this line of examination is objectionable, inasmuch as you didn't ask him anything about it on direct examination. However, under the new rules there is the right to recall the witness, and we can save that time here.

Mr. Morriss Sr.:—I thought it was a part not charged.

Mr. Brown:—That was charged particularly in the petition, about the yacht.

Q.—The boats that he went back and forth on to Europe were the best boats going and coming, as far as you know, weren't they fine, big ships? *A.*—He wouldn't be very apt to go in a tub, I wouldn't think.

THE COURT:—Now, Mr. Witness, I want to admonish you. You are supposed to answer questions here, not make an argument. That will be done by the attorneys.

The Witness:—I am sorry.

THE COURT:—Observe the court's ruling.

Q.—That ship, the *Normandie,* that is a big, fine ship, isn't it, Mr. Witness? *A.*—I think so.

Mr. Morriss Jr.:—We object to that as being a conclusion.

Mr. Morriss Sr.:—And it is immaterial and irrelevant.

THE COURT:—I think everybody can pretty nearly take notice of the fact that the *Normandie* is a big boat, probably a fine one.

Q.—What was the name of the other one, the one you went over in? *A.*—The *Queen Mary.*

Q.—Well, that is a big one and a fine one, too, isn't it, sir?

Mr. Morriss Jr.—The same objection.

Q.—Is that right?

The Witness:—Do I answer?

THE COURT:—Yes, go ahead and answer.

A.—I should think so.

Q.—And on the *Normandie* he had the most expensive and biggest suite of cabins, their biggest ones on the boat, didn't he?

Mr. Morriss Jr.:—Just a minute. This witness is not shown to be competent to testify to that.

THE COURT:—What is the materiality?

The Witness:—I wouldn't be—

THE COURT:—Counsel, what is the materiality in that?

Mr. Brown:—They allege that—that is part of the article upon which they allege and are suing us for damages for saying that. We just want to show that it was so.

THE COURT —I believe the article said he travels abroad and returns to this country in the finest suites and finest boats Overrule the objection

Mr Brown —And that is the portion ——

Mr Morriss Jr —Our objection is the witness is not shown to be competent to testify, and it would be a conclusion and opinion on his part

THE COURT—About what?

Mr Morriss Jr —Whether the most expensive and finest

THE COURT —If he doesn t know he can say so, but counsel can have him describe the suites

Q —How many rooms did you have in the suite for instance on the *Normandie*? *A* —We had two rooms a room for the boy and I and a room for Dr and Mrs Brinkley

Q —Were they little bitty staterooms where you had to crawl up one over the other to get in bed, or what kind? *A* —Nice sized rooms You didn t climb up

Q —Twin beds in them? *A* —Yes sir

Q —Or little beds? *A* —They had small single beds

Q —Did you have a living room and dining room in that same suite? *A* —On one of the ships I believe we did

Q —Which one, the *Normandie*? *A* —Yes

Q —And what kind of rooms did you have on the *Queen Mary*? *A* —Well we had double rooms, a room for the boy and I which had single beds and a room for Dr and Mrs Brinkley which had single beds

Q —Did you have a living room or dining room, anything like that? *A* —No

Q —Those suites on those ships Mr Witness were handsomely furnished, fine stuff in them *A* —I don t know whether I am competent to judge on that

Q —You know the difference between broken down furnishings and nice ones? *A* —Things were comfortable enough both ways

Q —Weren t they handsomely furnished? You know enough about things that you can say whether they were furnished in fine style or not? *A* —Well, naturally, any first class cabin on a ship of that kind is nicely furnished In my opinion you couldn't get anything else

Q —Now, about how long did you work for Dr Brinkley altogether? *A* —Five years and two months I believe to be just about exact

Q —That is, you have been a tutor for his son for that long? *A* —Yes, sir

Q —Did you start working for him after he came to Del Rio? *A* —No sir, I went to work for him in Milford, Kansas, just a few weeks before he came here

Q —Are you still working for him? *A* —No sir

Q —When did you quit? *A* —December 1st

Q —Last December 1st?

The witness then stated that he is now in the life insurance business in Council Grove, Kansas

RADIO BROADCASTS

At this time the court and the lawyers considered the question of the order of the court to Brinkley to produce either transcripts or victrola records of his broadcasts from the station in Mexico Dr Brinkley stated "I don't know anything about it I imagine the records prepared in 1938 have all been destroyed I don't think the station keeps them over two or three months after they are filed over there"

After much discussion about getting the records or transcripts of the broadcasts, the court said

THE COURT —It seems to me as a practical matter that this should be handled very simply Everybody knows Dr Brinkley for years has been broadcasting over the radio I hear it all the time running around in my car I have always understood and I presume it is true, that he doesn t personally go over and do it that frequently he sends records over there If that is true why not say so and if he can get the records all right If we can t we will have to handle it some other way Why make trouble about it?

Mr Morriss Jr —We hadn't intended to make trouble about it I wanted to explain that to the Court We hadn t intended to make any trouble about it at all we just didn't construe—

THE COURT —If they are over there will you try in good faith to get them?

Mr Morriss Jr —Yes, sir, we will

Next came the discussion of the number of depositions which would be introduced by the attorneys for both sides and as to what the court would permit in the introduction of depositions

Second Day, March 23, 1939

On the beginning of the second day, the plaintiff rested his case, at which time Mr Matthews, attorney for the defendant, introduced a motion for a directed verdict in accordance with the new federal rules that permit the making of such motions at the close of plaintiff's evidence

Mr Matthews said

However preliminary to that we would like to call your honor's attention to what we consider to be a contempt of this court and conduct on the part of the plaintiff here requiring that this case be discontinued On last night the plaintiff in this case Dr Brinkley over the radio that he regularly broadcasts over made derogatory statements with respect to the defendant in the case mentioning him by name He made derogatory statements with respect to the American Medical Association and made statements generally referring to and having a bearing upon the case now on trial In substantiation of that we would like to call Dr Brinkley

THE COURT —What is before the court about it? Is it your idea that the trial is prejudiced by what he has done?

Mr Matthews —Your honor, it seems to me to broadcast over a powerful radio station one of the parties get on a powerful radio station during the trial of the case, and broadcast over it during the trial is obviously contempt of court

THE COURT —You make a motion and have him cited and I will hear that separately and apart from the case If any of the jurors heard the broadcast and were swayed by it that might be grounds for a motion for a new trial

Mr Matthews —What we want to do is to make a motion in contempt and call this to the attention of the court and ask that a mistrial be declared at this time

THE COURT —I am not going to declare a mistrial on it unless I am advised that some of the jurors heard or were influenced by it I don't think it is wise during the course of the trial to stop and go to interrogating the jury about that

Mr Matthews —I think that is correct, your honor

THE COURT —And the question as to whether they heard the broadcast and whether they were influenced by it is one that could come up on a motion for new trial, but if I stop now and start trying the jury out on what they heard if anything, and whether it had any influence on them would militate against the trial The jury ought not to be poked around during the trial of the case

Now, with regard to the matter of whether the taking of the air and making a broadcast of that kind constitutes a contempt of court and whether civil or criminal I will hear you on that if you make a motion and require them to answer, when this case is over

Mr Matthews —Now, your honor—

THE COURT —I am not going to attempt to pass on the matter in advance, but I will certainly say to counsel for the plaintiff, who of course should have advised his client, inasmuch as you heard the court admonish the jury to refrain from talking or listening to any one about it and even not to read the newspapers it is certainly poor judgment to go upon the air with the case during the trial of the case I don't suppose counsel is responsible for that

Mr Morriss Sr —First I ever heard of it is right now Of course, we never in any manner anticipated it We will inquire of Doctor about it

TESTIMONY OF JOHN R BRINKLEY

Mr Brown, attorney for the defendant, then called to the stand John R Brinkley, the plaintiff The evidence proceeded as follows

Examination by Mr Brown

Q —What is your name, please? *A* —John R Brinkley

Q —Where do you live now, please, Doctor? *A* —Del Rio, Texas

Q —And do you operate a hospital here in Del Rio now? *A* —Not now

Q —You operate one, as I understand in Arkansas, Little Rock Arkansas? *A* —Two hospitals, yes sir

Q —Doctor, without stating the exact date, about how long have you been practicing medicine? *A* —Since 1915, since 1915

Q —Yes sir Now when did you first commence to advertise yourself as a doctor? *A* —I think I began radio talks about our hospital in 1929

Q —Well had you issued any pamphlets—first, when did you first do the goat gland operation, taking a piece of goat testicle and putting it in— *A* —I got—

Mr Morriss Jr —Just a moment We object to that as being irrelevant and immaterial to any issue in the case, as being remote, too remote for consideration here, and as not bearing on any issue in the case

THE COURT —No counsel, I think that if the plaintiff doesn't offer himself as a witness the defense under the rules has a right to call him, cross examine him just as fully as if he had taken the stand on his own account

Mr Morriss Sr —We think so, too

THE COURT —And that is what they have done Now, he put the matter in issue here as to his reputation What he has done his qualifications, all that sort of thing and they are entitled to search it thoroughly So I overrule your objection

Mr Morriss Jr —I would like to be heard

THE COURT —I have just heard you

Mr Morriss Sr —May it please the court, there is a matter that I wish we might state to the court, remind the court of That is, there is no evidence whatever from the plaintiff concerning this matter, except on cross examination they asked plaintiff's witness if during all the time since 1933 that he had been with the doctor any such practice had prevailed, or any such operation, and he said no The undisputed testimony therefore is that now to go back to some remote time for them to prove the matter of the experiments with the goat glands would be too remote here It is a question of his practice now

THE COURT —I don't think so They have charged Dr Fishbein charged in this article that this man was a quack engaged in quackery, and I think they are entitled to show anything with regard to his practice that will throw light on the matter Overrule the objection

Mr Morriss Sr —If it is not too remote Note the exception

THE COURT —A man that comes into a libel suit practically puts his entire life in issue

Mr Morriss Sr —We don't think that is correct, your honor

THE COURT —It is a question of his reputation If it is damaged, how much it is damaged Overrule the objection

Mr Morriss Sr —If it is a question of reputation we make the added objection that that is too remote and must be proved also by general reputation and not by specific acts

THE COURT —All right

Mr Morriss Sr —Note the exception

Q —When did you first do the operation of taking a testicle out of a young goat and putting in the testicle of a man? *A* —1917

Q —And how long did you continue to do that operation? *A* —Up until the end of 1932, beginning of 1933

Q —When did you first open, when did you move to Milford, Kansas, and start practicing there? *A* —1917 Yes, 1917

Q —1917? *A* —Yes

Q —Did you advertise by pamphlets, newspaper advertisements, or any other way before you started broadcasting? *A* —Yes

Mr Morriss Sr —Will your honor note our exception goes to all this?

THE COURT —If you want to make an objection you had better make it

Mr Morriss Sr —I hate to interrupt

THE COURT —It is your province to interrupt

Mr Morriss Sr —Anything back of—I mean back of 1930, we would object to as being too remote That is the objection we make, the objection to this, it is too remote

THE COURT —Overrule the objection

Q—You say you started broadcasting, first, in answer to my question, when did you start advertising yourself as a doctor? You said you started broadcasting in 1929 Now, I want to ask you if that is when you started broadcasting, have you advertised yourself as a goat gland specialist before 1929? *A*—Yes, sir, I advertised myself as a specialist on gland transplantation before 1929

Q—When did you start advertising? *A*—I can't be sure Some where around maybe 1921 or 1922, somewhere around there.

Q—And when did you build a hospital in Milford, Kansas? *A*—1917

Q—1917? *A*—Yes, sir

Q—Now, in those advertisements did you hold out to the world that the goat gland operation would make a man young sexually again?

Mr Morriss Sr—Just a moment May it please the court, that would be the same objection, it is too remote, and for the further reason that it doesn't call for the best evidence or wouldn't be the best evidence

THE COURT—Overrule the objection

Mr Morriss Sr—Exception

Q—Now, just a minute In those advertisements that you issued about the goat gland operation from 1917 to 1929 when you started on the radio, did you hold out to the world that that goat gland operation would make a man sexually young again?

Mr Morriss Sr—Just a minute

Q—Or words to that effect?

Mr Morriss Sr—Just a moment

THE COURT—I have overruled your objection once

The Witness—I don't remember

Mr Morriss Sr—The record wouldn't show any objection to this question I don't want to interrupt I wish we might have it understood that the court would allow us to have an objection to all this same line

THE COURT—Well, the court has to have an opportunity to rule on whatever is presented Under the new rules you don t need to take an exception

Mr Morriss Sr—If it is a different objection we will make it but otherwise we would not have to

THE COURT—It is your duty to except if you think anything is improper It is no reflection on you to except, I mean to object

Mr Morriss Sr—I am not speaking about the exception, I am speaking about the objection I hate to be interrupting

THE COURT—I don't know any way you can avoid it It is the court's idea that these parties are entitled to go into this man's professional record, his reputation, both on the issue of any compensatory damages and on the issue of actual damages, also on the question as to the truth of the allegations contained in the article declared on I don't think they are limited as to time by the last few years

Mr Morriss Sr—Well, we think there is a reasonable limit

THE COURT—For instance, suppose a man has been practicing twenty five years without a license at all You could show that if you charge he is a quack, an unethical practitioner

Mr Morriss Sr—That is the point we want to be heard on because we think the court is in error on that and that is the very point I want to be heard on

THE COURT—State it now What is it?

Mr Morriss Sr—I will ask co counsel—

THE COURT—No, counsel, we have to proceed here in accordance with the rules of the court I will hear you if you want to be heard but don't call your co-counsel

Mr Morriss Sr—He has the authorities on it, but I may say this just as a matter of principle For instance, we know that there is always a limit in time upon which you may inquire It is a matter, as the court said a while ago, which relates to a question of character or reputation. For instance, we know that if you had a witness on the stand in any criminal case you may in criminal cases in Texas inquire about indictments and such as that within a certain period, but that is limited If it is more than seven years ago it is too remote, it is too much against the presumption of the law that a person has changed in that respect, and here this charge against him is that he is doing he is now guilty of this, that and the other, and of course to go back to the days of experimentation would not be proper if they are remote For instance, I might have tried and lost a case or done most any matter in the way of error, or I might have been incompetent, we will say, and then I might have gained competency in the practice of law, and it is the same way with a doctor, the same way with any and every professional man, and so it isn t proper to go back to a remote time to ask about this here, and moreover, here are the specific things that are charged in this libel, certain statements they made in this article are charged upon, many others are not They have to be confined to a reasonable period of time and to—and of course—I started to say this, that the proof of the truth of any other allegation doesn't help, I mean any other accusation in the article doesn't help upon this I do not have in mind right now the style of the United States Supreme case where there is a comment on the fact that it is an old custom to try and certainly a wholly unwarranted one, to try to prove the truth of certain things in the article in justification when the matter to be proved the truth or falsity is the particular portions of the article that are charged It doesn t matter that he may have told the truth in other parts of the article if he then slanders or libels him, any other parts of the publication go out, and those that are charged upon and nothing else are the ones, so we say that the lapse of time is such that that is too remote and therefore—and that moreover that isn't a part of the charge in this case, and to prove that doesn't disprove the libel which is sued on here, or to adduce testimony with regard to it, and therefore we say that is calculated to simply prejudice the rights of the plaintiff and all that testimony we will say it is calculated to prejudice the rights of the plaintiff, and it is irrelevant, immaterial and incompetent to establish or disprove the allegations in this case, and entirely too remote

THE COURT—Overrule the objection.

Mr Morriss Sr—Note the exception

Q—Doctor I will ask you that question again, if you please? *A*—I don t remember that I ever sent out any literature specifying I would make an old man young or anything like that

Q—Did you say in any literature that the goat gland operation would be an aid in impotency *A*—Very likely I did

Mr Morriss Sr—Now he is asking again what he said in literature, and the literature is the best evidence

Mr. Brown—This is the man that had it put out

Mr Morriss Sr—That doesn't relieve it

THE COURT—Overrule the objection

Mr Morriss Sr.—Note the exception

A—I can't remember the contents of the literature I mailed out years ago, it would be utterly impossible for me to testify to its contents

Q—But you do remember, don't you, if you please, in advertising the goat gland operation to the world for ten years, up until 1929, say, when you started on the radio, isn't it a fact you told the people of the United States that if they would let you operate on them with a goat gland it would aid impotency?

Mr Morriss Sr—The same objection, your honor

THE COURT—Overrule the objection

A—Yes, I think I recommended the implantation of goat, sheep monkey glands, as an aid to sexual weakness

Q—You did that in numerous pieces of literature you put out up to the time you started broadcasting in 1929, did you, Doctor? *A*—Very likely thousands of them

Q—It is the fact you did, didn't you, please? *A*—I mailed out a lot of literature advertising this gland work I was doing, running into thousands of pieces of literature

Q—And you got back thousands of letters through the mail didn t you, asking about it, before you started on the radio? *A*—I received a lot of mail, yes, sir

Q—Now, you quit the goat gland people, as I understand it—when did you quit fooling with the goat gland proposition?

Mr Morriss Sr—We object to that—when did you quit fooling

Mr Brown—I beg your pardon

THE COURT—I think the form of your question has an air of levity

Mr Brown—I beg your pardon

Q—When you discontinued the use of the goat gland operation, when was that? *A*—1933

Q—1933 Now, from the time you started in in 1917, up to 1933 how many of those operations, about, did you perform? *A*—Several thousands of them

Q—Did you make people pay up money for it, charge them for it? *A*—No, the—

Q—I don't mean— *A*—The gland tissue was an adjunct to something else

Q—When you used the goat gland operation did the patients pay you for that work? *A*—I didn't sell them an operation for a gland operation alone The gland was used in conjunction with other work I was doing as an adjunct to other surgery.

Q—Did you charge them for that? *A*—They paid for the glands and other work at the hospital, it was all together paid for

Q—Did your literature say that the four phase operation, at the time you had the goat gland operation, that the whole operation, and for the guaranty, you charged them $750? *A*—That is right

Mr Morriss Sr—Just a minute We are going to make an objection and move that that be excluded, for all of the reasons we did before

THE COURT—Overrule the objection

Q—Well, you say several thousand you operated on What is your best recollection as to whether that means two or three thousand or five thousand? I don't know what your best recollection as to how many people you operated on when you used the goat gland operation is

Mr Morriss Jr—Now, of course, we just have to object to questions that pertain to the goat gland operations

THE COURT—Well, if you think it improves your situation any do it

Mr Morriss Jr—Well, we object to it, if the court please

THE COURT—It seems to me that you have a good many objections to this kind of evidence. If there is any merit in one, one is just as good as forty, so far as the record is concerned

Mr Morriss Jr—We don't want to be put in the attitude of waiving by the failure to object.

THE COURT—I have tried to indicate to you the court's view about the matter This article, you yourself read all of it and if you haven t read it all the court would have let the defendant read it He is charged there with a good many more things than you declare on They go way back into his history in that article and charge him with matters, and those matters are pertinent and relevant to matters now being inquired about and when he alleges he is an ethical practicing doctor and his reputation is being damaged and he has been injured, he puts that in issue, and they are entitled to inquire into it Now, that is my idea, and that is why I rule the way I do, and I tried to make it clear to counsel Now, if you want to persist in making these objections it is your duty to do so if you think it will help, but it isn't helping the trial along any

Mr Morriss Jr—We just want it understood we are not waiving our objection to all of this line of testimony

THE COURT—You can state that in the record, but the court is not making any agreement with you

Mr Morriss Jr—We want it understood, then—

Mr Brown—No, we don't like to appear to be permitted by the word understood

THE COURT—I am not making any agreement at all

Mr Morriss Jr—Then we will have to object, and we object to this being too remote

THE COURT—Overrule the objection

Q—You said you had operated on several thousand people using the goat gland operation?

Mr Morriss Jr—The same objection

Q—Will you please give us a better idea as to what you mean by several thousand? *A*—Well, I have in mind five or six thousand people

Q—Five or six thousand people? *A*—Yes, sir.

Q—And during those years when you were sending out that literature you sent out thousands of pieces of literature, didn't you, telling people that that goat gland operation, in connection with the operation was a great success?

Mr Morriss Jr—Now, we object to that because any literature would be the best evidence, and that it is immaterial and irrelevant to any issue in the case, and too remote

THE COURT.—Overrule the objection

A—Yes, I told them that the operation was a great success, yes

Q—And after using it from 1917, up to 1933, why, you don t use the goat gland technic any more, do you? *A*—It isn t necessary to transplant glands any more, because we have commercial glandular preparations that we can buy on the market and inject to take the place of the glandular transplantation

Q—The question was you don't use the goat gland operation, haven t used it since 1933, have you? *A*—That is right

Q—Now, when you started broadcasting in 1929—by the way, before you started advertising as a doctor were you a member of the American Medical Association? *A*—Yes, sir

Q—And then isn't it a fact that the ethics of that association are opposed to a doctor advertising himself and saying he is the best doctor and that he can cure you? In other words, the ethics of the American Medical Association are opposed to a doctor advertising himself, isn't that correct?

Mr Morriss Jr—Just a moment We object to that as calling for a conclusion and opinion of the witness, and not being the proper standard or criterion of what would be proper in the case

THE COURT—Overrule the objection

A—My understanding is that the ethics of the American Medical Association are opposed to any form of advertising by any physician

Q—Yes, sir Now, after you started broadcasting in 1929 and that was when you operated, then, in 1929 1930, 1931, 1932, and quit in 1933, the goat gland operation, did you tell the people on those broadcasts during those years, did you tell them about the goat gland operation? *A*—No, sir, I didn't

Q—Not over the radio? *A*—No, sir, I never said anything about the goat gland operation over the radio on none of my broadcasts

Q—During the years 1929 to 1933, when you were still using it, did you still put out literature? *A*—Yes, sir

Q—Telling about the goat gland operation? *A*—Yes, sir

Mr Morriss Jr—The same objection

THE COURT—Overrule the objection

Q—In other words, you advertised yourself and the goat gland operation in printed advertisements, is that right, up to 1933?

Mr Morriss Jr—Same objection, if the court please

A—Yes and no There is some period in there, I don't remember just when it was, when the earlier literature, as I remember it, I am just trying to give you an idea—

Q—That is the literature you put out? *A*—I know what you are driving at, and I am trying to help you out

Q—Well, I thank you very much *A*—I am not trying to hedge at all

Q—All right *A*—The earlier literature was built around a gland operation and the gland operation was, we will say, the star of the literature, and then the gland operation was minimized and the prostate work for enlarged prostates began to become the star in the literature to where the gland operation in the literature began to take a back seat, if you will pardon me for such a homely illustration

Q—It had the front seat for ten years or more, didn't it? *A*—No, not ten years, it didn't have the front seat that long

Q—What did you say in the literature from 1929 to 1933, when you stopped using the goat gland operation, what did you say in the literature about the goat gland part of it? *A*—I don't think I said very much about the gland operation at all in the literature If I had one of the little blue books I used to mail out we could look at it and see

Q—Is this the one about your health—is this the one you mean? *A*—Let's see if this is the one I am trying to think about There is something that I have in mind here that I was trying to point out to you I think this is what I am getting to

Q—Is this the one? *A*—Here is what I am getting to You see here is the book I am thinking about where all I say about the glands, I discuss it here on page 25 to 26 Gland transplantation, the compound operation is the outgrowth of experiments

At this point Dr Brinkley identified the various pamphlets which he has been using from time to time, including those sent from Kansas, pamphlets entitled "Rejuvenation," "The Compound Operation or the Modern Passport to Successful Rejuvenation," the pamphlet entitled "Recharge Your Batteries," the advertisement headed "Every Man Past Forty Should Know the Truth," the pamphlet entitled "The Brinkley Hospitals," the book entitled "The Life of a Man," postal cards used in circularizing patients, also advertisements which had been published in various newspapers

The testimony then proceeded as follows

Q—Doctor, are you the most learned physician in the United States? *A*—No sir, I don't think so

Q—Haven't you claimed to be the most learned physician in the United States? *A*—No

Q—Haven't you claimed to be the greatest surgeon in the world? *A*—Maybe some people writing for me have, but I haven't myself

Q—Well this chapter in your book here, isn't it a fact chapter nine is entitled "The most learned doctor in America"? *A*—It may be It may be what Mr Wood put in it, that biography

Q—With the copyright held by your wife's sister? *A*—That is Wood's conception of it

Q—Isn't it a fact that on page ten here, or page 110, it says speaking of you, 'Dimly he had begun to realize that he was gifted beyond the run of doctors" Isn't that in your book? *A*—Maybe, I don't remember

Q—And here at page 200, doesn't it say "I'm going to show the American Medical Association, and the doctors and people of this country, that John R Brinkley has more medical knowledge than any of them have shown"? *A*—I never said it Probably Wood did

Q—You are going to disclaim everything that appears in your biography? Are you or not? *A*—I am—

Mr Morriss Jr—We object to that as being argumentative

Mr Brown—I withdraw that question, if the court please

Mr Morriss Jr—His biography—

THE COURT—The question is withdrawn, counsel

Q—Isn't it a fact on page 203 you said you are going to show "to the jealous organized doctordom in America that he was more qualified than any of them"? *A*—No, I never said that It may be in the book Wood may have said it, but I never said it.

Q—Page 214, doesn't the book say here, "in his presentation of facts no matter on what subject, he is a student of human nature, a psychologist a master showman, as well as one of the world's most learned doctors and surgeons"? Isn't that in your book?

Mr Morriss Jr—We object to counsel continuously putting into the question "your book"

THE COURT—Let's find out something more about the book, its connection

Mr Morriss Jr—It is composed and written by another person

Mr Brown—No, I asked—

THE COURT—Let's find out whether it was published under his authority or not, whether he knew about it, whether he ever repudiated it or anything You haven't gone far enough with it

Q—Is there a new edition of this book, a later one than this? *A*—Yes, sir

Q—When was the latest one published? *A*—I declare I don't know. About two years ago, I think something like that

Q—Has it got a blue back on it, has it a stiff back? *A*—It has a cover on it something similar to this

Q—Well, hasn't it got a stiff back like an ordinary book? *A*—No The one with the blue back is the first edition

Q—Oh *A*—That is the first one

Q—That is the one which is stiff like an ordinary book? *A*—Yes, bound in cloth

Q—Where did the man get the facts from that wrote this book? *A*—Well, he collected them up from different places I employed him to write a biography of myself

Q—I see *A*—And I don't know he asked me and he asked my wife, he asked people that were acquainted with us He went back to North Carolina where I was born and you might say made a research of me, and then he wrote this book

Q—Have you ever repudiated this book? *A*—No, I haven't repudiated it

Q—Did you pay him for his work? *A*—Yes, sir, I paid him to write it

Q—Did you read any of it? *A*—Yes, sir

Q—Did you read all of it? *A*—No, I don't know as I have read all of it, but I have read a lot of the book

Q—And you hired, you employed him to write it for you? *A*—That is right

Q—*And you paid him for writing it*? *A*—I did

Q—And you have had how many editions issued, altogether? *A*—Three or four, I think about four editions

Q—And you are selling the latest edition of it right here in Del Rio now, aren't you? *A*—No, sir

Q—Who is selling the latest edition? *A*—Nobody

Q—It is out of print, is it? *A*—No

Q—Where could we get the latest edition? *A*—You would have to get them from the printer, I guess, in Kansas City, Missouri We don't have any of them on hand here

Q—Sir? *A*—I say we don't have any of them on hand here in Del Rio, because we don't do any mailing from Del Rio, you see

Mr Brown—Your honor, I think that connects it sufficiently

THE COURT—How has the book been distributed?

Q—Who has sold the book? *A*—I gave it away, what was distributed I never sold the book The first edition—

THE COURT—You sent it out as an advertisement?

The Witness—No, I just sent it out to people to let them read it. A lot of people write to me and ask me a lot of questions

THE COURT—All right, go ahead and ask him your questions I believe the last matter before the court was counsel's objection to your asking him about what was in the book I overrule that objection

Q—Doesn't it say in the book on page 310, quoting the "splendid words of Sidney Lanier 'What possible claim can contemporary criticism set up to respect—that criticism which crucified Jesus Christ, stoned Stephen, hooted Paul for a madman, tried Luther for a criminal, tortured Galileo, bound Columbus in chains, drove Dante into the hell of exile and committed so many other impious follies and stupidities that a thousand letters like this could not suffice even to catalogue them?' Of their company is John R Brinkley" Isn't that in your book on page 310? *A*—Probably is, yes, sir

Q—Yes, sir Doctor, I want to ask you now about some things the book says about the goat gland proposition, about what you claim about the goat gland proposition, or rather operation, as to whether it includes sexual powers, that is what I want to ask you about Now, on page 95, isn't it a fact that the book says, in speaking of the goat gland operation, when you first considered, "it was such an easy field, he knew, for any practitioner to hold out false hopes to a troubled patient, and charge him almost anything Other doctors had told him how the suckers bite, at any bait, when they are troubled in this vital aspect of their own manhood" Is that in your book at page 95? *A*—It very likely is, yes, sir.

Q—Were you the first man that ever did this operation of taking the goat testicle and putting it in the man's testicle? Were you the first man that ever did that? *A*—So far as I know I was, yes, sir

Q—Does your book state here at page 101—you remember you operated on two old farmers first, didn't you, two old farmers?

Mr Morriss Jr—We make the same objection

Q—At Milford, Kansas—

THE COURT—Overrule the objection

Mr Morriss Jr—It is too remote, irrelevant, immaterial and a specific instance rather than a general matter

A—The first man I operated on was 45 years of age, and I think the second man I operated on was about 38 years of age

Q—Were they troubled with loss of sexual power. *A*—Yes, sir

Q—What effect did the goat gland operation have on them? *A*—They claimed complete restoration of their sexual powers

Q—Then did you operate on two people kind of having trouble with their minds? *A*—Yes, sir

Q—And the fifth operation, was that on a boy when you passed a barber shop and heard them making fun of the operation? Did you take a young man out and operate on him, or rather did you operate on one of the boys that was there in the restaurant or barber shop? *A*—I think the third operation was a cashier in a bank that went insane.

Q—I say you had two farmers and then two that were troubled in the mind, and was the fifth one a man around Milford, when they were kind of laughing about the operation? *A*—Oh, I know who you mean, old Charley Tasine The boys in the barber shop were kidding Charley, whether he would have an operation or not, and he said he would if he had the money, he would have an operation, and I was coming along, and I said, "You don't have to have any money, come up to the hospital and I will give it to you for nothing"

Q—And you gave it to him? *A*—Yes, sir.

Q—You took him up and the operation was entirely successful, wasn't it? *A*—Yes, sir He was a bachelor and he got married right afterwards, anyway

Q—Didn't the book say on page 101 that "the man to whom Doc had done this had become a regular billy goat, twice as good as any other man around Milford"? *A*—That is what he claimed He was one of these boasting fellows liked to blow off as to his ability.

Q.—About that time you owed some money on your hospital, didn't you? *A.*—Yes, sir.

Q.—And you hired a publicity agent to come down there and help you advertise, did you? *A.*—I hired a man that had had experience in advertising to come down there and advise me if there was anything I could do to increase my business.

Q.—Yes, sir, and didn't he ask you, "Well, you are just a country doctor here away out in the country. What has happened here unusual, what has been done here that we can advertise?" Didn't he ask you about that? *A.*—Yes, he did.

Q.—And finally after your studying around about it didn't you tell him about this seven, I think it was, operations you had performed with the goat gland operation, or whatever number it was? *A.*—I don't remember whether I had seven at that time—

Q.—I don't mean the number, if you will excuse me, but didn't you tell this advertising man finally, "As far as doing anything different, I will tell you, I have done this goat gland operation"? *A.*—That is right.

Q.—And didn't he reach over and grab you by the hand and say "Well, we have them, it is worth a million dollars"? *A.*—He said, "Dr. Brinkley, you have something that is worth a million dollars to you."

Q.—Well, it has been worth a whole lot more than that, hasn't it, Doctor?

Mr. Morriss Sr.:—That is irrelevant and immaterial.

Mr. Brown:—We say he has been getting the shekels out of the people.

THE COURT:—I think it is a matter of argument. You were asking about the goat gland operation. Sustain the objection.

Mr. Brown:—You sustain the objection?

THE COURT:—To that question, yes.

Q.—The book here on page 155 quotes from you; it says "I began removing several inches of the vas deferens, lymph chain and vas deferential artery, together with a crown suture through the pampiniform plexus located in the epididymis; and in addition to this surgical technique the transplantation of the testicles from the three-weeks-old Toggenberg goat. Needless to say, the results were astonishing, miraculous." That is in your own words, isn't it, Doctor? *A.*—Yes, sir, I have seen astonishing and miraculous results, yes, sir.

Q.—Now, I don't mean to go into technical details of it. Let me ask you this. I may have it wrong in my mind. *A.*—All right.

Q.—Is it a fact that in operating on the goat gland operation, as I understand it, and please correct me if I haven't got it right, you didn't remove any of the testicles out of the man, did you? *A.*—The ordinary goat gland operation is what you are thinking about, isn't it?

Q.—Yes. *A.*—Certain ones I took and cut a hole out of the man's testicle and took a chunk out and filled the hole up in the testicle with goat gland.

Q.—Ordinarily you would cut a little flap or slip? *A.*—Just a pocket to put the gland in.

Q.—Would you put a piece of the goat gland in that little hole? *A.*—No. A 3 week old goat, I would use a 3 weeks old gland, just take the capsule off of the gland and transplant the whole gland.

Q.—You would put a goat testicle in one man's testicle and another in the other side? *A.*—Yes, and sometimes put them in the abdominal muscles. There were different locations for them.

Q.—Now, Doctor, we say in this piece that you are suing us about here, one of the things that you are suing us for, it says that the effect of it is that since you started advertising the goat gland operation that you have made lots of money. That is a fact, isn't it? *A.*—I think that is something we all have to argue about, whether a fellow makes lots of money or not.

Q.—I don't mean whether you have spent it or spent it on expenses or used bad judgment as to what you did with your money, but this says this, it says "he continues to demonstrate his astuteness in shaking shekels from the pockets of the credulous Americans." In other words, that is one of the things you are suing us about, is whether you have gotten lots of money out of the American people, isn't that a fact? *A.*—Well, it is the way you state it; shaking shekels is entirely different, to my way of thinking, a different expression than "you have made a lot of money by operating on people."

Q.—All right, over here there is another place that they allege on where it says it has been reported that at some times you have made as much as $55,000 a week. "The evidence assembled indicates that at various times Brinkley has made as much as $55,000 a week as a result of his various quackeries." *A.*—I never made anything like $55,000 a week. I wish I had.

Q.—You stated that you operated on five or six thousand for the goat gland operation, and the main operation was $750. *A.*—Yes, but only a small per cent pay $750.

Mr. Morriss Jr.:—We object to going into that. It is irrelevant and immaterial to any issue in the case, as to what was made out of it or what profit was made out of that, and we make that additional objection.

THE COURT:—I think the authorities all hold that the entire article is admissible. If you can cull certain parts out and say they are false and libelous, they have the right to put in the whole article for the purpose of seeing the drift and purpose of the entire writing.

Mr. Morriss Jr.:—Yes.

THE COURT:—And while the fact part may be true wouldn't relieve them from responsibility for that part which is false, still in an effort to show the article is substantially or wholly true, I think they are entitled to take it up entirely. Overrule the objection.

Mr. Morriss Jr.:—If the court please, we think these matters, other matters, unless they reflect light upon the particular part charged on, are improper to be gone into.

THE COURT:—I know, but the question is the damage this man suffered, that is in the case, and you can't compress it into any narrow confines and get a just trial, and I think that they have put him on the stand and that allows them to do it. They are entitled to go into the matter very fully and ventilate it if they want to, so I am going to overrule the objection.

Q.—Doctor, I am not asking you now about your net income report or your report to the government or anything of that kind, but I want to ask you what was the gross income, the total income of yourself and your wife for the year 1938?

Mr. Morriss Jr.:—We object to that as being immaterial and irrelevant and improper and incompetent.

THE COURT:—Counsel, I ruled on your matter. You and I have an entirely different conception of the ruling with regard to preserving your record. I think if you make it clearly known to the court that you object to a certain line of procedure and the court overrules you and announces that that line of procedure is to go on, you have done enough. You seem to think you have to get up and make an objection every time a question is asked. I think you had better look at that new rule.

Mr. Morriss Jr.:—I think this was a different question.

THE COURT:—The point about it is, it is militating against the trial in two ways. In the first place, it is taking a lot of time and, in the second place, it is so breaking up the thread of what is sought to be brought out that the jury and court and everybody else loses the natural continuity of the story, and I am going to ask you to consider that rule and see if you think it is necessary for you constantly to do this. I know the nature of your objection. I told you what the court's ruling is. I have gone to the trouble several times to outline to you my idea as to what I think the course of the trial ought to be. If it is contrary to your idea, why, after having stated your reasons, don't you let it go at that? The record is going to show what has transpired. I don't think it is necessary for you to interrupt every time anybody does anything.

Mr. Morriss Jr.:—If the court please, we thought this was a different line of questioning, and we think it is because, in the first place, as I understood counsel, it related to 1938. Is that correct?

Mr. Brown:—Yes, sir.

Mr. Morriss Jr.:—Which was subsequent to the time of the article.

THE COURT:—I don't see the difference. I ruled they could inquire into the money he made out of these operations that were a part of his advertising campaign. The mere fact they confine it to one year doesn't change the ruling. I am going to have to ask you to help the court a little bit. I don't want to appear to be querulous or arguing with you, still you will have to assist in the trial of this case. Otherwise we will be here too long.

Mr. Morriss Jr.:—We were under the wrong impression a while ago.

THE COURT:—I know, but there doesn't seem to be any way to get rid of you. Every time I say something it provokes a new argument out of you.

Mr. Morriss Jr.:—Well, I didn't want to be put in the attitude of waiving any matters, and secondly, with reference to this, we thought it was an entirely different matter and inquiries as to his general income.

THE COURT:—That is the fifth time you told me it was a new matter. If you think that is helping us to go forward, I don't see it.

Mr. Morriss Jr.:—We except to the court's remark.

THE COURT:—All right.

Q.—What was the gross income of yourself and your wife for the year 1938? *A.*—Our gross income for the year 1938, from all sources—I can't give you the exact figures because my auditors make this out—is around $810,000 gross.

Q.—Yes, sir. Now, what was your gross income for the year 1937? *A.*—If I remember correctly, the gross income for 1937 was pretty close to eleven hundred thousand, right at $1,000,000 gross. Either it was a little over ten hundred thousand or a little under, I just can't remember those exactly, but I have it, of course, at my office in Little Rock. I have copies of my income tax return. That would give the dollars and cents.

Q.—You took a trip one time on a boat to China, didn't you, you and your wife? *A.*—That is right, yes, sir, in 1923.

Q.—And you had had a great deal of unfavorable publicity in the papers before you took that trip, hadn't you?

Mr. Morriss Sr.:—Just a moment. We think—

THE COURT:—I think the question is argumentative.

Mr. Morriss Sr.:—Besides, it refers back to a time in 1920 or '21. I believe he said. It is very, very remote.

Q.—It is a fact that before, just before you took that trip and while on that trip you had a great deal of very unfavorable comments in the newspapers, but—

Mr. Morriss Sr.:—Just a moment. If so, that would be hearsay and not binding on this plaintiff.

THE COURT:—You can ask him if he had been commented on in the newspapers just before he took the trip. I don't know what you are leading up to.

Mr. Morriss Sr.:—Let it be understood that we object to it primarily because it is too remote and not an issue in this case and collateral, immaterial and irrelevant.

THE COURT:—Overrule the objection.

Mr. Morriss Sr.:—And hearsay, of course.

THE COURT:—Overrule the objection.

Q.—It is a fact, is it not, that before you took that trip and when you were on that trip the newspapers commented very widely on you in an unfavorable way? *A.*—No, sir, I don't think that happened until after I was in China. I think it broke loose after I left.

Q.—Doesn't the book say it was before and the passengers even shunned you on the boat? *A.*—Oh, Lord, no. Oh, no, the comment about the passengers on the boat was we were guests of the captain of the steamer and there was a certain amount of jealousy due to that.

Q.—You tell about full dress dining with the captain, don't you? *A.*—Yes, sir.

Q.—Doesn't it say on page 166, "All aboard!" And then it says that "at the very time when he was completing his plans to go to Shanghai, at Dr. Thompson's invitation, to operate on wealthy Chinese sufferers"? And then it says "These flaming headlines in every paper against him made it practically impossible for him to secure patients in America." Don't you remember that those newspaper attacks were on you before you left for China? *A.*—No, I don't think they really got started until after I got over there. I don't think they had.

Q.—All right. Excuse me. *A.*—I ought to have—I am not trying to dodge the issue, but that is my impression. You will probably have copies of those newspapers, and it will give the dates.

Q.—I just read this part out of the book. Doesn't it say on page 157 "Unfortunately, the provincial-minded Americans on board were jealous at these attentions, and left the Brinkley party pretty much to itself"? *A.*—That was on account of the captain being so solicitous to Mrs. Brinkley and setting aside reservations in the picture show, and he ignored the rest of the passengers, and I think they resented so much attention being paid to us by the captain of the ship.

Q.—Now, as to this article in the *Hygeia*, published by the American Medical Association, it is a fact, is it not, Doctor, that the newspapers and magazines of this country on several occasions have commented most unfavorably about you and your work?

Mr. Morriss Jr.:—We object to that as a conclusion, calling for a conclusion and opinion of the witness, and would not be the best evidence and is irrelevant and immaterial and incompetent to establish any issue in the case, and hearsay.

THE COURT:—This is cross examination here, in effect, under the rule. Overrule the objection.

Mr. Morriss Jr.:—Note the exception.

A.—I think that what adverse criticism that I have read in the magazines and newspapers concerning me has probably had its basis in statements from the American Medical Association, which they used as an authority in denouncing me.

THE COURT:—Doctor, he didn't ask you that question.

Q.—I asked you isn't it a fact that at different times up to the time that this article was published the newspapers and press of the country have attacked you very severely, you and your work? *A.*—I don't think the press of the country knows it. The Kansas City *Star* put on—

Q.—I am just asking you, if you please, about the press of the country. You can say no if you like. *A.*—I would say no to that, that is the way I would answer that.

Q.—Do you remember what they call the diploma mill scandal? *A.*—Yes, sir, I do.

Q.—Isn't it a fact that the newspapers of the country in this diploma —what do you mean by diploma mill scandal? What is that, please? *A.*—It refers to a situation that was existing pretty much all over the United States, and I believe its headquarters were in the state of Missouri. There was some understanding between certain people operating medical schools in the state of Missouri and secretaries of state boards of the various states where that somebody that didn't have the proper qualifications or something like that would buy or get a degree from one of these schools and then by some aid from somebody get by the board.

Q.—In other words, they would get their diploma without studying like they are supposed to do, but by paying in some way, they would get a diploma when they were not entitled to it? *A.*—Some hocus-pocus, yes, sir.

Q.—That is what you called the diploma mill scandal, wasn't it? *A.*—Yes, sir.

Q.—And that was pretty widely discussed throughout the country in the newspapers, wasn't it? *A.*—Yes, sir.

Q.—And in connection with that didn't the newspapers charge you, that you had gotten your license and your diploma in this diploma mill route, that they turned out the diplomas like a mill ground them out?

Mr. Morriss Jr.:—We object to that. It is not the best evidence and is hearsay, calls for a conclusion and opinion and not competent to establish any issue in the case and as being too remote and is an improper attempt to show reputation by specific, any specific instance, and show truth by hearsay.

THE COURT:—What do you say about that, counsel?

Mr. Brown:—Well, your honor, just in mitigation I want to show that at former times during his professional career—he is complaining of damages by reason of this article, and certainly we have a right to go into whether the other papers have commented on his standing, in mitigation of the damages.

THE COURT:—All right, overrule the objection.

Mr. Morriss Jr.:—Note the exception.

Q.—Isn't it a fact that you became branded from end to end of the land as a diploma mill graduate?

Mr. Morriss Sr.:—Just a moment. If the court please, we make the same objection for each and all of the reasons just now given, and the inquiry is not directed as to any particular time and it is in no way shown that it is or could in any way be proved in mitigation, as counsel said was the purpose, of damages in this case because of the remote time and that some other paper may have done, and of course that further calls for a conclusion and is argumentative.

THE COURT:—If these facts be true wouldn't they be entitled to be considered with regard to the motive and intent of the defendant Fishbein in making these charges, as to whether or not he had grounds upon which he honestly believed them?

Mr. Morriss Sr.:—I shouldn't think for a moment—

THE COURT:—The authorities have held that.

Mr. Morriss Sr.:—I shouldn't think for a moment a publication back in 1920, we will say, whether it was right or wrong, whether slanderous or not, by somebody else could be put in evidence to mitigate damages for a libel published in 1938. I wouldn't think so, your honor.

THE COURT:—Overrule the objection.

Mr. Morriss Sr.:—We accept.

At this time a short recess was had, at the conclusion of which the following proceedings were had, in the presence of the jury:

THE COURT:—All right, read the last question.

The reporter thereupon read the last question, as follows:

"*Q.*—Isn't it a fact that you became branded from end to end of the land as a diploma mill graduate?" *A.*—I couldn't say that I was branded from one end of the land to the other as a diploma mill graduate. I know the newspapers carried a lot of articles about me being connected with a graduate of that school.

Q.—That they called a diploma mill? *A.*—Yes, sir.

Q.—And those pieces appeared all over the country in papers, didn't they, Doctor? *A.*—I am quite sure many, many papers carried it, yes, sir.

Q.—Isn't it a fact that Henry Ford's Dearborn *Independent* carried a lengthy attack on you and he called you the dean of quacks?

Mr. Morriss Sr.:—The same objection, may it please the court, the same objection.

THE COURT:—Overrule the objection.

Mr. Morriss Jr.:—At the same time we make—

THE COURT:—Please observe the rule as to only one counsel.

A.—In 1923—

Mr. Morriss Sr.:—Of course, we make the motion as to this and all matters that have preceded it on this question wherein the attempt to get that in under the guise of mitigation, we make the motion first that it be excluded and the jury instructed not to regard it for any purpose, for all of the reasons that we have stated an objection to it, and secondly, that as to each and all of it that it be limited and the jury be instructed so that they may understand that it is limited to the purpose of mere consideration, and cannot be had for any other purpose on this than the subject of mitigation.

THE COURT:—Well, I think it is admissible not only from the standpoint of mitigation but it is admissible as going to the good faith of the defendant in the matter, as to whether he actually believed what he was writing.

Mr. Morriss Sr.:—Then limited to those purposes—

THE COURT:—If you want it limited that way the court will limit it that way.

Mr. Morriss Sr.:—We want it limited only in the event the court overrules our objection, which we consider good, and admits it.

THE COURT:—I will overrule the objection and limit it to those purposes.

Q.—Dr. Brinkley, the Kansas City *Star*, what town is that published in, Kansas City, Kansas or Missouri? *A.*—Kansas City, Missouri.

Q.—And what has the daily circulation of the Kansas City *Star*—what is that circulation, do you know? *A.*—I think it was 245,000 at that time.

Q.—When you were practicing there in Kansas the Kansas City *Star* was attacking you in various ways, was it not? *A.*—Daily, yes, sir.

Mr. Morriss Sr.:—Just a moment. The same objection, it is too remote for any purpose here.

THE COURT:—Overrule the objection.

Mr. Morriss Sr.:—That is among all of the others.

Q.—Do you know whether the Kansas City *Star* was read in every state in the union? *A.*—I don't know what their circulation—I don't know where they went to.

Q.—Yes, sir. They would write up these things, put them on the front page, wouldn't they, the Kansas City *Star*? *A.*—Many of their articles were on the front page.

Q.—Now, were the papers at the time of those attacks by the Kansas City *Star* on you, did the papers of the country have headlines about your alleged fakery, quackery and fraudulent activities?

Mr. Morriss Sr.:—Same objection, your honor.

THE COURT:—Overrule the objection.

Mr. Morriss Sr.:—Also it is a conclusion and hearsay.

A.—For some strange reason the papers over the country didn't seem to copy these articles out of the Kansas City *Star* and reprint them. Very few were printed by other papers. I had a clipping bureau to see what distribution there was over the country of those articles at that time, and it seemed it was confined mostly to the Kansas City *Star* itself.

Q.—Isn't it a fact that the papers all over the country carried pieces about your alleged fakery, quackery and fraudulent activities? *A.*—I suppose many papers did.

Q.—Isn't it a fact, Doctor? *A.*—I wouldn't say a fact.

Q.—I don't mean every paper. *A.*—I don't know the extent. When I say papers all over the country carried it I would be saying every paper over the United States.

Q.—No, I don't mean that, but papers generally? *A.*—No doubt many papers.

Q.—Carried articles accusing you of being a fake and quack and things of that kind? *A.*—I think many papers did.

Q.—Yes, sir. In the American Medical Association—what is that, please, what is the American Medical Association? *A.*—Well, the American Medical Association, I believe, is a corporation incorporated under the laws of the state of Illinois with principal offices at 535 North Dearborn Street, Chicago, and it publishes a weekly medical journal and other publications, including *Hygeia* Magazine.

Q.—How long have they been— *A.*—And they publish a medical directory.

Q.—How long has the American Medical Association been in existence, do you know about how long? *A.*—I don't know whether they were organized in 1856 or 1876.

Q.—Isn't it a fact, Doctor, that most of the regular physicians throughout the United States are members of that association?

Mr. Morriss Sr.:—We object to that as being immaterial and irrelevant to any issue here.

THE COURT:—Overrule the objection.

Mr. Morris Sr.:—Note the exception.

A.—My impression is about 80,000 physicians belong to the American Medical Association, and I think the total number of physicians in the United States is somewhere around 140,000 to 150,000. That is what is in my mind. It may be more than that, because I am not in a position to be an expert on how many doctors there would be. That would be for Dr. Fishbein to say.

Q.—You haven't much opinion for the activities of the American Medical Association, have you? *A.*—In some respects I don't like their activities.

Q.—Do you think most of the men in the association instead of being Christian gentlemen as of old, they are politicians and abortionists, do you think that is what the members of the American Medical Association do?

Mr. Morriss Sr.:—We object to that as being immaterial and irrelevant to any issue in the case, as to what he would think.

THE COURT:—Sustain the objection.

Mr. Brown:—We except to the ruling of the court.

Q.—What was your income in the fiscal year 1936? *A.*—I couldn't tell you that.

Q.—You don't have an approximate idea about it? *A.*—No, I don't remember what it was.

Q.—Whether it was a half million or a million? *A.*—I would have to get the information from my bookkeeper.

Q.—You can't remember whether it was a half a million or a million? *A.*—No, I can't.

Q.—All right. Dr. Brinkley, so that you will understand it, if you please, the first paragraph of the article says this, "He continues—" that you are suing on the part of the article—I will say this so you will understand what I am asking you about in these questions. It says, "He continues to demonstrate his astuteness in shaking shekels from the pockets of the credulous Americans, notwithstanding the efforts of the various governmental departments and agencies." Now, throughout your practice the governmental departments and agencies have tried to stop you from these advertisements, and as far as your license and broadcast is concerned they have been opposed to you, haven't they, the governmental agencies? *A.*—No, sir, not that I can think of.

Q.—That is the way you want to answer it? *A.*—Yes sir.

Q.—All right, sir. Well, you had, at one time you had a license to practice medicine in the state of Connecticut, didn't you? *A.*—Yes, sir.

Q.—The state examining board of Eclectic, the Eclectic board after an investigation and hearing, they revoked your license to practice in Connecticut, did they?

Mr. Morriss Jr.:—Just a moment. We object to that as being immaterial and irrelevant and incompetent to establish any issue in the case, and that any order which was made by the board would be the best evidence and that it is incompetent to establish any issue in the case and would be hearsay and incompetent and prejudicial to the rights of the plaintiff.

THE COURT:—Overrule the objection.

Mr. Morriss Jr.:—Except.

Q.—It is a fact that your license to practice medicine in the state of Connecticut, after investigation that your license was revoked, was it not? *A.*—No investigation was made.

Q.—Well, it was revoked? *A.*—They were revoked, yes, sir, when I was in China. I never was even called before the board or an investigation made. They put out a blanket order and revoked the licenses of every Eclectic doctor in the state of Connecticut, some having been licensed there for fifty years.

Q.—Your license in Connecticut was revoked? *A.*—Yes, sir.

Q.—You had this radio station in the state of Kansas? *A.*—Yes, sir.

Q.—Were you operating that station under permit of the United States government? *A.*—Yes, sir.

Q.—That permit was issued under what they call the Federal Radio Commission? *A.*—At that time, yes, sir; Federal Communications Commission now.

Q.—Now, how long, altogether, did you operate your Kansas station? *A.*—*It was built in 1923 and I sold it in 1931.*

Q.—When did the federal government revoke your radio license or refuse to renew the license of your radio station in Kansas? *A.*—They refused to renew the license in June 1930.

Q.—June 1930? *A.*—Yes, sir.

Q.—Now, is it a fact that a reporter for the *Star*, the Kansas City *Star*, that this reporter was a great booster of President Hoover in the Republican convention when Hoover was first elected President?

Mr. Morriss Jr.:—I don't see any pertinency, your honor.

Mr. Brown:—I will show it, your honor, *in just a moment.*

THE COURT:—Unless you can indicate some pertinency to it it seems to be going too far afield.

Mr. Brown:—I want to ask him if he didn't accuse President Hoover himself, after he was President of the United States, of influencing the Radio Commission to revoke his license, showing under our allegation here you have done these things even though the governmental agencies and governmental departments have tried to stop you.

THE COURT:—All right, overrule the objection.

Mr. Morriss Jr.:—Note the exception. We move the court now to instruct the jury not to consider these remarks.

THE COURT:—Yes, the jury will, of course, realize that the remarks of counsel are not evidence. You will not consider his remarks as evidence, it is simply made to assist the court in ruling on the objection.

Mr. Brown:—Yes, sir.

THE COURT:—*You will be governed by what you hear from the witness* stand. Go ahead.

Q.—What was the man's name, do you remember it? He was a prominent reporter on the *Star* that was one of the first promoters of the—of President Hoover's campaign for the presidency. Do you remember the name of that reporter? *A.*—No, sir, I do not. May I help you out a little bit? I think you are thinking of the managing editor of the *Star*, Mr. Roberts, that was the promoter of Mr. Hoover's campaign. It never occurred to me it was a reporter. I think it was Mr. Roberts, the managing editor of the *Star*.

Q.—He was a great supporter of Mr. Hoover's? *A.*—Yes, sir.

Q.—Then Mr. Hoover appointed some members of the Federal Radio Commission, did he not? *A.*—I guess he appointed them all.

Q.—Yes, sir. *A.*—I think he did.

Q.—Is it a fact that even President Hoover himself, when this controversy *came up about refusing your license in Kansas, that he advised* the Radio Commission that they ought to revoke your license or influenced the Radio Commission?

Mr. Morriss Sr.:—Now, may it please the court, that would be the rankest hearsay.

THE COURT:—I think you would have to show this witness knew it of his own personal knowledge.

Mr. Brown:—I will show that he has charged that in a document which he has ——

THE COURT:—Then ask him about that, don't ask him this as a matter of original evidence.

Mr. Brown:—Yes, sir.

THE COURT:—Sustain the objection.

Mr. Brown:—Note the exception.

Q.—Isn't it a fact that on page 229 of your book in reference to when they were having a hearing about renewing your license it was stated, "and the *Star*, as the A. M A. and everybody knew, was very close to the new president; and, in turn, he held a position of advantage over the Federal Radio Commission." Didn't you state that in your book? *A.*—Yes, sir.

Q.—And didn't you say "That was the set-up. It was inevitable that the A. M. A. would seek the help of the *Star*. It was inevitable that the *Star* would throw itself enthusiastically into the fight. There *are things in history that never see the light of day.*" McDonald is the name of that reporter I was thinking about. Was there a reporter named McDonald? *A.*—Yes, sir, that was one of their reporters.

Q.—It is a fact, then, that you claim in the book here that the President himself interested himself with the Radio Commission to get your license revoked, isn't that a fact? *A.*—Yes, sir, that was told to me by Vice President Curtis, is where I got my information.

Q.—Vice President Curtis told *you the President himself had interested* himself? *A.*—Yes, sir.

Q.—And the Radio Commission had a hearing with respect to renewing your license, did they not? *A.*—Yes, sir.

Q.—And the Radio Commission of the United States government refused to renew your license in Kansas, did they, Doctor? *A.*—Three did and two didn't.

Q.—But the majority refused to renew your license? *A.*—Yes, sir.

Q.—Now, you have had a pretty severe contest in reference to the state board or authorities out there in California, didn't you? Didn't you apply for a permanent license to practice in California? *A.*—Yes, sir.

Q.—You practiced there a few weeks under a temporary license, didn't you? *A.*—Yes, sir.

Q.—Made $40,000 there, didn't you? *A.*—I don't recall what the gross returns were.

Q.—Something like that, wasn't it? *A.*—I consider it was something like that, yes.

Q.—*Then* after you came back to Kansas isn't it a fact that you were indicted in California and that they sent the officers out to Kansas to bring you back to California?

Mr. Morriss Sr.:—Just a moment. The same objection, that is, the objection that it is immaterial and irrelevant and incompetent to establish any issue in this case, doesn't show any character of wrong upon his part or any character of impropriety or unethical conduct, and it is hearsay.

THE COURT:—What character of indictment was that?

Mr. Brown:—Practicing medicine in conspiracy with another fellow, another doctor, contrary to the laws of California.

THE COURT:—Overrule the objection.

Mr. Morriss Sr.:—And the fact that that happened—in other words, an indictment is no presumption of any man's guilt of anything.

THE COURT:—I think that is perfectly true, counsel, but when you are inquiring into the question as to the intent and motives of a party in writing an alleged libelous article, and when you are inquiring into it not only from the standpoint of a basis of compensatory damages, but you accuse *him of malice and ask for exemplary* damages, you are entitled to put yourself in his place and see what light and information he had that he thought was true that would warrant him in writing this article, and accordingly you are on a different footing. Overrule the objection.

Mr. Morriss Jr.:—But we do move that it be definitely understood as not being admissible except—

THE COURT:—As not being admissible for the purpose of proving the alleged indictment, but simply on the question of mitigation and the question of the good faith of this party in writing this article. All right.

Q.—Well, that is a fact, isn't it, Doctor, you were indicted in California and they sent officers back to Kansas to try to take you to California *A.*—Yes, sir.

Q.—And you were very much displeased with the activities of the United States government in reference to refusing to renew your radio permit, were you not? *A.*—Displeased?

Q.—Yes.

Mr. Morriss Jr.:—The fact that he was displeased is irrelevant and immaterial.

Mr. Brown:—Your honor, it is under the question of the activities of the governmental agency.

THE COURT:—Whether he is displeased or not, what would that tend to prove? *It naturally follows that if he wanted his license renewed* and they wouldn't renew it he wouldn't like it, but I don't like the form of your question.

Mr. Brown:—All right the question is withdrawn.

Q.—Isn't it a fact you stated and circulated matter in reference to your contest with the governmental departments—that you state in this book and circulated that California has a legal record for persecution that stinks to Heaven? A.—It probably is in the book, yes, sir.

Q.—"*Tom Mooney is still in jail there. The United States has a* legal record for persecution that stinks to Heaven." Didn't you put that in about your government with reference to this, and didn't you put that in the book and circulate the book? *A.*—I think it is in there, and the book was circulated.

Q.—There it is—"the United States has a legal record for persecution that stinks to high Heaven." That is in there, isn't it, Doctor? *A.*—Yes, sir.

Mr. Morriss Sr.:—We move the exclusion of that for all of the same reasons and for the further reason it is shown that the article or book is not written by Dr. Brinkley but written by a wholly different man.

THE COURT:—I know, but the doctor said he paid the man to write it. He read it and has been giving it away.

Mr. Morriss Sr.:—He said he read parts of it. He made the statement he never had read it.

THE COURT:—That goes to the weight of the evidence rather than to the admissibility. He is circulating the book, he says he is giving it away. I think that is legitimate examination. Overrule the objection.

Mr. Morriss Sr.:—Note the exception.

Q.—Now, after the Federal Radio Commission refused to renew your permit in Kansas you appealed that case to the Court of Appeals of the District of Columbia, didn't you? *A.*—That is right, yes, sir.

Q.—And that court agreed with the government? *In other* words, they sustained the action of the board in refusing to renew your permit? *A.*—Yes.

Mr. Morriss Sr.:—Same objection, may it please the court, and for the further reason that nothing of that matter is in the publication which is complained of, nor would it be the best evidence.

THE COURT:—Overrule the objection.

Mr. Morriss Sr.:—Note the exception.

A.—The court held with the commission, yes, sir.

Q.—And didn't you print and circulate in this book here throughout the country here that as far as your contest with the government departments was concerned, that the commission and the court ignored all the weight of the evidence, for they were out to get Brinkley? *A.*—Very likely I said that, yes, sir.

Q.—Now, then, you had a license, of course, to practice medicine in the state of Kansas, didn't you? *A.*—Yes, sir.

Q.—And was it the board of health of the state of Kansas *had a* hearing— *A.*—No, the board of medical examiners is the licensing body.

Q.—Of the state of Kansas, they had a hearing on whether they would revoke your license to practice medicine in Kansas, didn't they? *A.*—Yes, sir.

Q.—And you had been practicing medicine in Kansas since 1917, up to— *A.*—1930.

Q.—Was it in 1930 that they revoked your license to practice? *A.*—Yes, sir.

Mr. Morriss Sr.:—We make the same objection to all that, your honor.

THE COURT:—All right.

Q.—So this board who licenses people to practice medicine in Kansas, they had a *hearing in respect to your case*, didn't they, Doctor? *A.*—Yes, sir.

Q.—*And after that hearing* they revoked your license to practice medicine in Kansas, didn't they? *A.*—That is right, yes, sir.

Q.—Yes, sir, and after they revoked your license you appealed that case to the Supreme Court of the state of Kansas, didn't you? *A.*—No, I don't think it went to the Supreme Court of the state of Kansas. I think it went to some federal court.

Q.—Let me see. *A.*—I don't think it went to the Supreme Court of Kansas, I think it went to the federal court.

Q.—Isn't it a fact *that you appealed to the Supreme Court of Kansas* after they had revoked your license to practice medicine? *A.*—I don't think we ever went to the Supreme Court of Kansas after the license was revoked.

Q.—Well, isn't it a fact— *A.*—Maybe we did, but *it runs into my* mind that we went into a federal court.

Q.—I will ask you that in just a minute. Isn't it a fact that on page 244 you say "Meanwhile Brinkley's attorney went before the Supreme Court of Kansas and sought to prevent the hearing"? *A.*—That was before the hearing.

Q.—Oh, excuse me. You claimed that the members of the medical board of Kansas were so prejudiced against you they wouldn't give you a fair trial, isn't that right? *A.*—That is right.

Q—So you went to the Supreme Court of Kansas trying to have your case heard before somebody else or another board or something of that kind? *A*—I declare I don't know what went before the Supreme Court, I don't know what we went before the Supreme Court for.

Q—Anyway, you went before the Supreme Court of Kansas before the hearing? *A*—Yes, sir

Q—And isn't it a fact that in your book here at 244 you copy what the Supreme Court of Kansas said about your case, and didn't the Supreme Court of Kansas say this, or you said this, "The Supreme Court was hardly impartial in its denial of Brinkley's claim, since it went beyond the charges in purporting to express them, holding that they held that Brinkley was 'an empiric without moral sense, and having acted accordingly to the ethical standards of an imposter, the licensee has performed an organized charlatanism until he is capable of preying on human weakness ignorance and credulity to an extent quite beyond the invention of the humble mountebank' . who was 'fleecing the defective, the ailing, the gullible and chronic medicine takers who are moved by suggestion, and is scandalizing the medical profession and exposing it to contempt and ridicule'"? A—Something like that

Mr Morriss Jr—We object to that may it please the court, for the dual reason, first, that it was written in a book which is shown not to have been—he may have authorized it or assented to this man writing his biography and agreed to pay for the publication That doesn't mean he is the writer or author of it—

THE COURT—I have already overruled you on that question, counsel

Mr Morriss Jr—All right Secondly, the other matter is hearsay, and for the further reason it is simply quoting what some other concern said about him

THE COURT—As I understand it, the comment that counsel was just reading, is something that the Supreme Court said, is that correct, counsel?

Mr Brown—Yes, sir, copied by this man

THE COURT—And put in this book and circulated by Dr Brinkley

Mr Morriss Sr—Yes, sir

THE COURT—Overrule the objection I can't see why if the doctor put it in the book and circulated it himself he can take exception

Q—Now, since you have been here in Texas, isn't it a fact that the state medical board of Texas filed suit to revoke your license to practice in Texas? *A*—Yes sir

Q—And they filed that suit up in Dallas didn't they? *A*—No, here in—yes I guess it was Dallas Dallas, yes

Q—Now, in respect to this allegation here about the government agencies being against you his the American government itself, Dr Brinkley, been against you in your desire to practice medicine and your advertisements and your radio talks, has the American government itself been against you? *A*—Well I wouldn't know how to answer that question

Q—Well, isn't—don't you claim that the American government itself—well, I will just say here on page 276 of your book isn't it a fact you state, "The American Government itself now came out openly against" him? *A*—I think I was referring to the State Department, yes sir

Q—The State Department of the United States government? *A*—(No answer)

Q—Now, it says in the article, you see this first paragraph, it says that you are a quack and it said about making money Then we said in the article that the various governmental departments—that you kept on making money notwithstanding the efforts of the various governmental departments and agencies Then down here you also state that you have been damaged because the article says that when your radio station was removed from Kansas—don't you say from Kansas—"he departed to Mexico, obtaining a license from the Mexican Government" Now, when you lost your license to broadcast in Kansas, Doctor, it is a fact that you then went to Mexico and made arrangements for the station across the river from Del Rio isn't it?

Mr Morriss Sr—Same objection

THE COURT—Overrule the objection

A—Yes sir

Q—And you are now broadcasting from station XERA at Villa Acuna, Mexico? *A*—Yes sir

Q—Just across from Del Rio, Texas? *A*—Yes sir

Q—That is true, isn't it? *A*—Yes sir

Q—Isn't it a fact that "all sorts of efforts have been made to remove him from the air, but apparently without success," that is true? *A*—All sorts of efforts were made to remove me

Q—Here is one thing Dr Fishbein said in the article which you now complain of He said all sorts of efforts have been made to remove him from the air, but apparently without success'? *A*—Yes, I quite agree with that part of the article All sorts of efforts have been made to try to close me down put me out of business I agree with them

Q—So that is true, isn't it? *A*—I agree with Dr Fishbein on that

Q—Now, the article says—

Mr Morriss Jr—Just a minute In connection with that we would like to say "all sorts of efforts, that would necessarily mean by some particular person or individual The question would be on whose part If all sorts of efforts have been made by the American Medical Association, by Dr Fishbein, or at his instigation, why of course then it would perhaps be of some bearing, but if somebody else some wholly independent concern, we just think that that sort of thing, that that kind of statement is a shotgun statement and doesn't show anything about who made all sorts of efforts or at whose instigation, and therefore would have no place in this evidence

THE COURT—You seem to be in disagreement with your client He says he is heartily in agreement with it

Mr Morriss Sr—I understand, but we are talking about the legal aspect not talking about whether they were made, but it is not shown by whom

THE COURT—I don't know that I understand what the nature of your objection is what is before the court, but if you are objecting to that last question that was asked and the answer, I will overrule your objection

Q—Now in connection with the sentence in the article that you complain of is right now, that is, February 1938, "right now he is not doing much in the way of goat gland transplanting" That is correct, isn't it, Doctor? You weren't doing any at that time, were you? *A*—I haven't been doing any transplanting since 1933

Q—So that sentence is correct, "right now he is not doing much in the way of goat gland transplanting' Is that correct?

THE COURT—He answered the question, counsel Pass on He answered it

Q—Now, then, we come to this part here where it says "he reads" the article says, "he reads the symptoms of patients and then by remote control prescribes the pill that they should use" Well, isn't it a fact that people write in to you, ever since you have been broadcasting, they write in to you telling you of their ailments and symptoms and so forth? *A*—Yes, sir, they write to me but I don't go back over the radio and answer their letters and prescribe for them

Q—Don't you tell them over the radio what prescription to take? *A*—No sir

Q—Have you ever done that? *A*—Not since 1930

Q—Not since 1930? *A*—No sir

Q—Well, how do you then—do you have any prescriptions now that are numbered? *A*—No, sir

Q—When did you quit numbering your prescriptions? *A*—1930

Q—That is the last time? *A*—Yes, sir

Q—Do you sell 1022 now? *A*—No, I don't sell it

Q—Do you— *A*—Unless you can call selling—you come into my hospital and become a patient and I use it on you I sell it that way, but I don't sell it out through the mail or advertise it to mail to somebody, you send me so much money and I will send you 1020 I don't do that

Q—When did you quit? Say the folks would write in to you and say "I hurt so and so and my symptoms are so and so," and you would take the letter and read it over the radio on broadcasts and say, "I advise this lady to take prescription No 50" *A*—I quit that in 1930

Q—In 1930? *A*—Yes, sir I promised the Federal Radio Commission—we had the hearing in June 1930—that I wouldn't read those letters and prescribe any more over the radio, and I haven't since

Q—But how many years before 1930 did you do that? *A*—I only did it for about a period of six months I began it in the fall of 1929, and the whole thing was over in June 1930

Mr Morriss Jr—Now, then, we move the exclusion of that

THE COURT—Overrule the motion

Q—Did you ever advertise in any of your literature or say over the radio if the people would send a dollar or two dollars in that you would advise them what was the matter with them and tell them what medicine to take? *A*—No I said if anybody wanted a personal letter from me to send two dollars and I would write them a personal letter of advice I didn't say I would send anything I had to do that to overcome so many requests There were thousands of requests wanting me to write them something and it was utterly impossible to do it

Q—Now, then, here is another line you complain of "In addition of course, he has a hospital in Del Rio where he performs some peculiar operations" During that time back there before 1930, when they would write the letters and then you would prescribe over the radio, didn't you have an arrangement with the druggists throughout Kansas where they would have this medicine in the drug stores numbered Dr Brinkley prescription No 50? *A*—The druggist had the prescriptions I had the druggists in five states, which we would call the primary service area of the radio station In other words, our trade territory And these prescriptions were sent to the druggists for their files, so if you came in and said No 50 the druggist would mix it and compound it according to that prescription That is the way it was handled

Q—How many of those numbered prescriptions did you have, do you remember, about? *A*—It seems to me like they ran somewhere from one to fifty, something like that

Q—And the people would write in and then you would read the letter over the radio? *A*—Yes, sir

Q—And you would say "I advise this lady and people that are suffering like her to go to the drug store so and so," whatever drug store she lived by, "and get prescription number so and so"? *A*—No 50 or 60 or 70, whatever it was, yes, sir

Q—And, of course, you got some commission or divided the profits with the druggist, didn't you, Doctor? *A*—I didn't get a commission I had an understanding with the druggists that they were to send so much of their total weekly sales to be applied against the weekly broadcasts In other words, if that wasn't done he would be getting it for nothing

Q—In other words you made some money? *A*—I didn't make any myself, there was no intention to make money out of it It went to the station for operating expenses

Q—Now, the article said you operated a hospital at Del Rio That was correct, wasn't it? *A*—Yes, sir

Q—Now, it said "where he performs some peculiar operations" Well, the operation that you performed on the enlarged prostate, that was different from the standard operation performed for that by the regular doctors, wasn't it, Doctor? *A*—Well the operations I perform are different from the rank and file performed by the regular doctors. Of course, I do transurethral work—

Q—I just wanted to cover that point You performed operations here in Del Rio that were different from the regular standard practice, as you understand it? *A*—Yes, sir

Q—That was adopted by most of the physicians? *A*—Yes, sir

Q—That is true, isn't it? *A*—Yes, sir

Q—And the main one of these is what you call the compound prostate operation for elderly gentlemen, that was the main one, wasn't it? *A*—I call it the surgical technic It used to be called the compound operation

Q—And in which it says "He merely injects a little mercurochrome" You did in that operation, in many cases, inject some mercurochrome into the tubes passing from the main sex glands, didn't you?

Mr Morriss Sr—Just a moment, counsel He misconstrues the statement the way he words that

THE COURT—That is a matter of argument You will have an opportunity to examine the witness

Q—In some cases of course you would do more than inject the mercurochrome, is that right? *A*—In all cases I do more

Q—You do more? *A*—Yes

Q—All right Now, you don't collect from the patients yourself, do you, Doctor? *A*—No, sir

Q—You have some manager, business manager, that makes arrangements about getting paid for the work? *A*—That is right

Q—And do you usually inquire, ordinarily and usually do you inquire of your business manager to see whether your people can pay or will pay before the work is done? *A*—Yes, sir

Q—Ordinarily? *A*—No, sir

Q—Most of the time you do the work without knowing whether you are going to get the money? *A*—I thought you meant did we make inquiry to find out whether the patient had money or not

Q—No, sir Here a man comes, he wants to be operated on and you think he is going to be operated on, whether you endeavor, as a business man of course you endeavor to see if you are going to get your money if you operate on that man? *A*—That is right, yes, sir

Q —Now, in reference to these—you get a whole lot of letters, don't you? A —Quite a few, yes, sir

Q —And you answer—no, I believe you state now that you don't answer those letters over the radio? A —No, sir

Q —But you develop a lot of your business through the mail by correspondence and letters you get from people and letters you write to them? A —Yes, sir

Q —Now, since you have been in Del Rio you haven't used the goat gland operation, as I understand it? A —None whatever, no, sir

THE COURT —He has been asked about that several times, counsel Don't ask him about that again

Mr Brown —I beg your pardon

Q —You have been using what you call your new surgical technic What did you say awhile ago it was? A —Surgical technic, yes, sir

Q —Now, what has been the result in operating on the prostate glands by the use of this new technic? Has it reduced the enlarged glands? A —Yes, sir, it does

Q —Isn't it a fact that you claim that it clears the infection out of the entire human body? A —Not the operation itself but by the ministration of drugs and removal of focal points of infection—

Q —Excuse me— A —Let me explain something to you so you can ask me better questions When we speak of our surgical technic at $750 that not only refers to a man's prostate gland but refers to dental work and everything

Q —I understand about that A —We take a case to clean him up and we call that our surgical technic guaranteed service for lifetime That is what we are talking about, complete service for the patient for whatever he needs

Q —This book published in 1937, on page 301, don't you claim it greatly increases the sexual powers of men and women? A —Well, the work we do—

Q —No excuse me Didn't the book you published in 1937 say that? A —Probably it did

Q —Overcome depressed mental conditions, that is what you said in the book wasn't it? A —I think so yes sir

Q —Didn't you say in the book "He has, as a matter of cold sober fact, changed the color of his patient's hair, smoothed the wrinkles out of their faces and turned their complexions from a sickly pallor of old age and disease back to the ruddy glow of health"? A —That is true

Q —Is that true? A —Yes, sir

Q —What is the closest to $55 000 a week that you ever made? This thing says here it has been reported that sometimes you have made $55,000 a week What is the closest to that you ever got that you recollect? A —I don't think that I ever exceeded over $120,000 to $125 000 in a *month*

Q —In one month? A —So if we divided that by four it wouldn't be that much

Q —You don't think that Dr Fishbein ought to pay you any damages because he said you made $55,000 do you?

Mr Morriss Sr —Just a moment, that is argumentative

Mr Brown —I beg your pardon, your honor

Q —Doctor, you have been the possessor of three fine yachts, haven't you? A —Well I am happy—

Q —I say you have been the possessor of three fine yachts, haven't you? A —I own three yachts yes sir

Q —Well, how many men does it take to run the one you have now? A —It takes twenty one men

Q —A seagoing yacht? A —Yes, sir

Q —You don't want to say it is a fine yacht, do you? A —The one I have now is a mighty nice yacht, yes, sir

Q —Thank you Now, when you go and come across the seas on your summer trips you go in the finest boats, don't you? A —I try to go on good boats, seaworthy boats

Q —Are there any better boats than the *Queen Mary* or *Normandie*? A —If there were I would have been on them

Q —You go on the finest boats and stop in the best suite on the boats, don't you? A —I try to, yes, sir

Q —Isn't it a fact that for yourself and your wife and tutor and little boy you paid $1,900 to get from France back to the United States on the *Normandie*?

Mr Morriss Jr —We object to that as being irrelevant and immaterial

THE COURT —Overrule the objection

Mr Morriss Jr —Note the exception

A —I don't know what I paid the American Express Company I have an unlimited charge account with them, and after the trip was over five or six months later, they sent a statement in to me and my bookkeeper paid the bill

Q —You don't know whether it was $2 000 or $5,000, do you? A —No I suppose it was eighteen hundred or two thousand dollars, I suppose, something like that

Q —Well, in traveling across there on the boats do you and Mrs Brinkley talk to the passengers or not? A —Oh, some of them, if we meet them and get acquainted with them, yes, sir

Q —Doctor, the money is still rolling in to you isn't it, and you make most of your money out of the practice of medicine, don't you? A —Yes, my main income is from my hospital work

Q —And the money is still rolling in, isn't it? A —Well, I don't consider it that way

Q —I don't mean rolling in This thing here says rolling In other words, you are still making good money as a physician, aren't you? A —I have a nice practice

Q —Now, when you were here, when you were here in Del Rio you didn't have a separate hospital, did you? Was your hospital in the Roswell Hotel? A —That is right, we used three floors in the Roswell for hospital purposes

Q —Now, how many rooms does that downtown hospital have, the downtown hospital you have in Little Rock? A —Oh, about fifty

Q —How many patients will the downtown hospital accommodate? A —We can squeeze in forty

Q —Yes, sir Was that a two story building or a three? A —Two stories

Q —Was that an old building or was it constructed as a hospital? A —That was St Luke's Hospital, owned by one of the surgeons down there that died, and I bought it afterwards

Q —And then you have another hospital out in the country about sixteen miles? A —Yes We call that the Country Club Hospital

Q —That is an old *country club out there*? A —No, it was the Shriners' Country Club out there

Q —How many rooms has that got, about? A —You want to know how many patients I can keep out there?

Q —Yes, sir A —So I must tell you we can take care of about fifty patients out there It is in a *different arrangement* from the rooms at the other place There is a large receiving, reception halls, and dining rooms and dance rooms

Q —Do you own that? A —Yes, sir

Q —How many acres are there there? A —Three hundred and seventy five

Q —It was at one time used as a country club? A —I want to correct that statement You asked me if I owned it I don't know whether it means anything or not, but at least I want to try to tell the truth That is in a trust estate for my son, and I am the trustee and manage the trust estate Whether that makes any difference in the answer I don't know

Q —Now, those three floors that you say you had, did you have the whole of the three floors in the *Roswell Hotel here in Del Rio*? A —Well, we had all of the mezzanine floor, and if I am not mistaken I think—I think we had two floors above that, completely to our own use

Q —How many rooms were in there altogether? A —I don't remember We used the mezzanine for administrative purposes and operating room We had our sterilizing equipment and laboratory equipment in the basement

Q —Were any patients on the mezzanine floor? A —No, they were all examining offices and diagnostic offices and treatment offices and operating room and business offices and things like that

Q —Dr Brinkley, under this new technic I understood from Mr Petermeyer that testified yesterday, that you cut the ducts between the testicle and the epididymis, or the fold, or whatever you call it? A —No counsel, we don't cut, we ligate

Q —You tie it? A —Yes, a linen suture

Q —It is just the same as if you cut it, nothing can come through there? A —As long as the suture is on there the patient would be sterile Take the *suture off and he is fertile again*

Q —You say about fifteen of those little ducts from the testicles to the epididymis, each testicle has about fifteen Now, when you perform the operation do you tie all the little ducts between the testicle and the epididymis? A —In some cases they are all tied off In other cases only a part of them

Q —Well, didn't you say in your deposition that that—what was the name of that case Parnell case, when they took your deposition didn't you say three *different times* you *cut them* all you cut all of the efferent duct, tied them off, excuse me, ligated all of the efferent duct reaching from the testicle to the epididymis? A —If my memory hasn't gone bad on that deposition, I stated we ligated a part of that not all of them and I think the counsel asked me "Well how many?" and I said "Probably ten, eight or ten or eleven," something like that

Q —Isn't it a fact in *the deposition* you said three different times you ligated all of them? A —We do ligate all of them in certain cases yes, sir

Q —I can show you that, as to how it came up, as to that time Now isn't it a fact that in that deposition when they asked you about it you said "Question Now, what do you mean by ligating those ducts, state that technique to us please Answer Well, it is talking of the fifteen efferent ducts on each side approximately that number, tying off some of the sections of the testicle so secretions can't pass through the ducts to the epididymis I think that is about as plain as I can say what I mean by ligate Question Do you mean tie off with catgut or linen? Answer Yes, sir, we use linen And you sometimes tie of all fifteen of the efferent ducts Question Of both testicles? Answer That is right If *you don't do it on both* sides you might as *well not* do it at all Question Well, do you do it on both? Answer Yes, sir Question All fifteen ducts? Answer Yes, sir Question Do you ligate the vas as well Doctor? Answer No, sir Question That is the main tube that goes on up, isn't it"—excuse me just a minute A —I think I had already answered you

Q —I want to show how you answered *in the deposition* A —Yes

Q —Doctor, last Sunday night isn't it a fact you offered hundred dollar prizes over the radio to folks that would write the best letter on good health and send it to you and the names of two people that were sick and two people that had enough money to pay their way to Arkansas? A —I didn't specify the number

Mr Morriss Jr —Just a moment We desire to make an objection that that isn't a relevant time, that it is not a matter at the time that is in issue

THE COURT —Don't the courts hold these damages, if there are any damages, are not only retroactive but perspective?

Mr Morriss Jr —Yes, sir

THE COURT —The extent of the injury not only relates to the present and past but is carried forward to the future

Mr Morris Jr —Yes, sir

THE COURT —Accordingly, it would be proper to inquire as to the present condition, what he is doing, how his business is, and that sort of thing

Mr Morris Jr —We don't think it is proper to go into any matters now that wouldn't reflect upon, wouldn't shed any light on the issue of the damages at all

THE COURT —Well, the general allegation is made as to the lack of ethics and the fact that he is a quack I think what he is doing now would be relevant I will overrule the objection

Mr Morriss Jr —Note the exception

Q —That is a fact, isn't it, Doctor? On last Sunday night, substantially, you said you wanted to make a hundred dollar prize, to give it to the one that writes the best letter on health and sends to me the name of two sick people who are able or have money enough to pay their way to Little Rock, Arkansas? A —No, sir, that isn't the way I said it

Q —All right, how did you say it? A —I said "Next Wednesday we are going to divide one hundred dollars in cash into ten equal prizes

Q —Oh, yes A —*What I want you to do* is to take one sheet of paper and complete this in twenty words or less I consider *good health* my most valuable possession because—because what? Complete that in twenty words or less, on a separate sheet of paper send me the names and addresses of men that you are personally acquainted with that you personally know to be sick and in need of our services, physically and financially able to come to see us

Q —Physically and financially able to come *to see you where*? A —Little Rock, Arkansas

Q —Yes, sir And last night isn't *this* a part of your radio address last night, "Do you want to participate in the distribution of $500 cash without your having to send any bottle cap or carton or to buy anything just your intelligence? You are thinking we will listen on the air first This opportunity will close to you, but between now and April 30th there are going to be many men and women receiving distributions" You say I

that last night, didn't you, Doctor? *A*—I never heard the advertisement I don't know a thing about it All I can answer you about it is I told the announcer to make a contest along similar lines and $500 would be awarded May 5th

Q—Who was doing that talking you or— *A*—I wasn't over at the station, I wasn't over there I don't know, I guess Mr Don Howard, the announcer, I suppose

Q—They didn't use a record of your voice or anything of that kind? *A*—He may have Maybe I made a record before I left and went back to Little Rock I made a record last—I made a record last Monday morning and I think I put on that record—

Q—This $500 business? *A*—I believe I did

Q—All right And that came over the air last night, didn't it? *A*—I don't know, I never listened to the station If you heard it I guess it did

Q—Then you don't—excuse me "First prize $100 in cash, second prize $50, third prize $25, fourth prize $10 in cash five prizes of $5 each, and then 290 other cash awards of $1 each, 299 cash awards Each entry you send in has 299 chances to win as much as $100 in cash and listen, folks, it is easy All you have to do is think just think a little and be real sincere and real honest Here is the slogan, 'I consider Dr Brinkley the world's foremost prostate specialist because,'" and that is the blank? *A*—Yes

Q—And complete that in twenty words or less on one sheet That is the idea isn't it? *A*—Yes

Q—That is practicing medicine, isn't it? *A*—What?

Q—Practicing surgery, is that practicing medicine, practicing surgery, please? *A*—No

Q—All right, sir, "and complete that in twenty words or less on one sheet On the second sheet I want you to be real sincere and know what you are doing Just mail at least five names and addresses of men that you are personally acquainted with Be sure you know them be sure you know they are sick and be sure you know that they are in need of Brinkley's hospital service Be sure you know, be sure you know that they are physically and financially able to come to see us Just those five names and addresses on one sheet of paper You complete the slogan 'I consider Dr Brinkley the world's foremost prostate specialist because—blank—on a second sheet of paper, and send it to Dr J R Brinkley, Little Rock Arkansas and this prize ends April 30th and this cash will be distributed May 5th Now, folks, for your own health's sake, for your wife's sake for the sake of your loved ones, if sick don't neglect to send for the book Don't sit down there and listen to me and do nothing about it If undecided, don't know what to do, then listen, then listen to what you can do Come and see us I don't mean come see me or come to see the doctors and the nurses, come to see my patients We have two hospitals full of people Come in the front door or even in the back Meet the patients See what is happening to them They are just people like you And then decide what you want to do" Now, that was your advertisement that went out over the radio last night, wasn't it? *A*—I don't know whether it went out last night or not, but that is my advertisement, so what difference does it make?

Q—Probably this week? *A*—Yes sir

Q—And you send it out over this powerful radio station right across the river isn't it? Is that the station it goes over now? *A*—Yes

Q—How far will that reach, to Canada and all over the United States? *A*—It doesn't get into Canada because of a 50,000 watt station at Toronto knocks it out

Q—Practically all over the United States, is that right? *A*—Not in the East The primary service area of the station is a line drawn through Louisiana, Alabama, Georgia, up around through the Carolinas and Virginia and skirting Pennsylvania, a part of Ohio and across along the circular line passing through the Great Lakes and on down to the coast Of course, now, of a morning when we broadcast the Canada station is not on and the station will reach out all over the United States and Canada but I suppose you are talking about evening broadcasts

Q—Doctor, is this kind of advertising, is it usual for practitioners of medicine in the United States to conduct prize contests such as this? *A*—Not if they want to stay in the American Medical Association

Q—Excuse me Is it usual for practitioners of medicine in the United States to conduct these prize contests? *A*—No, sir, I don't think so

Q—Do you know of anybody else that is talking over big radios offering cash money? *A*—No, sir

Q—Do you know of anybody sending out certificates with red seals on them—give me that—with red seals on them, telling them, if you will come down to the hospital and write the best piece of any ten people we will put a seal on it like a notary seal tell them if they will do that, we will give them an automobile? *A*—No, I don't know of anybody doing that

Q—You are the only one doing that? *A*—As far as I know

Q—Isn't it a fact that on March 22, this year, that you sent out this broadcast over your station 'What is the use of trying to do anything when there is cancer in your prostate gland, because leaving that infection in there for years—there must have been something left out there—what are you going to do about it? You take a risk Why take a chance? You are sick and miserable Is your property doing you any good? Is that money doing you any good? Yet you have worked and made money, made property for the purpose of using it when you need it, and when a man and woman is sick is there any time in your life when you need to spend that money more than a time to get your health back? If you don't supply the money you are going to die You are not going to know health until your body becomes so diseased and so great a sum of money that you can't mortgage the property"—that must be left out— *A*—It is garbled

Q—Yes, I withdraw it "That is the picture that some men and women—of some men and women who neglect their lives poor houses at the end of the road and it might not have been, might not ever have been true if you had acted promptly That is, don't continue to take treatments that are doing you no good I believe that by the time of the end of this broadcast comes you are going to go and call or mail reservations to come to Brinkley's hospital in Little Rock as thousands of people have done and start life again down that road on the poor house This is Dr Brinkley urging you to do it now" There are some portions left out there *A*—It is garbled

Q—That is substantially it? *A*—Some of it is so and some don't make sense

Q—Yes I agree Did you ever say over the radio, Dr Brinkley, in effect Come to me and don't let your family doctor two dollar you to death'? *A*—Yes, sir

Q—How many times have you said that? *A*—I don't know how many times

Q—Throughout how many years have you said that? *A*—I only started that this year That is a new one

Q—Is it? How many times have you said it in the last year? That is, "Come to me, don't let the old family doctor two dollar you to death" *A*—I didn't say the old family doctor, I said don't let your doctor two dollar you to death I don't think I said old family doctor

Q—You didn't want to say that, did you? *A*—Oh, I wouldn't say that

Q—Oh Doctor, now, where do you claim, please, that you got your medical education? *A*—I had three years in Bennett Medical College, one year in Eclectic Medical College in Kansas City, Missouri

Q—When did you go to Bennett? Was that in Chicago? *A*—Yes, sir I matriculated in 1908 and left there when the junior year was over, about the 1st of June 1911

Q—Did you go to one right after the other? I mean no skipping there, three solid years? *A*—1908 to 1909, the freshman year solid, 1909 to 1910, sophomore year, was solid, and from the fall of 1910 to 1911 I missed about six weeks of the first part of junior year and didn't get back into school until some time, I think, around the early part of November

Q—Now, where were you during those six weeks that you missed? *A*—Telegraphing in New York

Q—For whom were you working? *A*—Western Union

Q—Do you remember what months those were? *A*—I went down to New York—I think I went down from Montreal, I was telegraphing in Montreal, and I left Montreal, I think it was around September, and went down to New York and resumed work for the Western Union there until some time in November

Q—About how long had you been in Montreal? *A*—I went to Montreal when I got through with my sophomore year in the summer of 1910, and I spent the summer up there

Q—And then you missed, you say, some of the fall term, about six weeks? *A*—Yes, sir

Q—And then you completed your junior year at Bennett College at the end of the spring term? *A*—Yes, sir, in 1911

Q—And when did you go to this Kansas City Eclectic College? *A*—1914 to 1915

Q—So you skipped how many years in there between the Bennett College and the Eclectic College? *A*—Well out of school in the summer of 1911 and not back in school until the fall of 1914 That was three years

Q—And during that time what were you doing? *A*—During the summer of 1911 and fall of 1911 I was practicing medicine in western North Carolina where I was born and raised, by permit of the secretary of the medical board, who knew I was an undergraduate Practiced there until some time, I think it was in October of 1911, going down to Jacksonville, Florida, for a couple of weeks, where I worked for the Western Union Telegraph Company, and left there and went to Whiteville, North Carolina

Q—When was that do you remember? *A*—Well, I think I went to Whiteville, I think I landed in Whiteville right close to the end of 1911 I can't be sure

Q—Yes sir *A*—And that has been so long ago, twenty, nearly thirty years ago I am trying to give you approximately

Q—All right, sir *A*—And some time in there some place I left Whiteville, I don't remember when, I can't remember when I was there, and I went up to St Louis, Missouri, and stayed around there for a short time and came on back to Tennessee, went to Danrich, Tennessee, practiced medicine at Danrich during the summer of 1912, the summer of 1912 I was practicing medicine at Danrich Tennessee During the fall of 1912 I moved down to Knoxville, Tennessee and I practiced around there somewheres toward the close of 1912 and the beginning of 1913, some time during the beginning of 1913—

Q—Now, you didn't have a regular license at that time, as I understand it? *A*—I had a license, undergraduate's license

Q—All right *A*—I had an undergraduate's license in Tennessee I was practicing legally

Q—Did you ever work and practice down at Greenville? *A*—I opened an office there for another man I never practiced there, never have practiced there

Q—What was the man's name? *A*—Mr Burke

Q—What was your partner's name in that venture? *A*—His name was Crawford

Q—Isn't Burke and Crawford the same man? *A*—No, Mr Burke was the owner of a chain of medical offices over the country

Q—What kind of diseases did that chain treat? *A*—Treated two, gonorrhea and syphilis

Q—Now, when you were there at Greenville, that institution you opened up at Greenville, they had paid ads in the paper advertising they would treat gonorrhea and syphilis, didn't they? *A*—I can't remember

Q—What was the name of the institution, the branch office you opened up at Greenville? *A*—The Electro Medic Specialists I think that is the name of it

Q—Do you remember whether—do you remember whether you did any advertising there? *A*—Oh, yes, there was many newspaper advertisements run

Q—Electro Medical Doctors? *A*—It might have been doctors

Q—Where was the store located? *A*—You mean the office?

Mr Morriss Jr—Just a minute It seems to indicate that this was not advertising Dr Brinkley, he was not—this was advertising of some body else, where he simply went to open the place of business for him, so it isn't a question of what the advertisements say for the other doctor, or some other doctor We think that that wouldn't have any bearing here, and besides it is far too remote

THE COURT—Overrule the objection

Mr Morriss Jr—Note the exception

Q—Well, it is a fact that you went down there to Greenville even while just a student doctor, before you ever got your diploma you went down there to Greenville working for a man that had a chain Was that fellow Burke a doctor? *A*—No, sir

Q—And he had these offices in different towns? *A*—Yes, sir

Q—And they treated gonorrhea and syphilis? *A*—That is right

Q—You went down there and opened up to start the office for him in Greenville, North Carolina? *A*—South Carolina

Q—And when you opened up and got ready to start, isn't it a fact you put big ads in the newspaper that you were opening up this office for the treatment of gonorrhea and syphilis? *A*—I know advertisements were run in the paper announcing the opening of the office That is what my business was, to advertise the opening of the office

Mr. Morriss Sr —In connection with that we want to make certain objections I guess your honor wants to quit now

THE COURT —You have made your objection and it was ruled on

Mr Morriss Sr —There is further matter coming on We will try to find out just what it is

THE COURT —We will take a recess

At this time a recess was taken until 2 p m of the same day, at which time the following proceedings were had, in the presence of the jury

Questions by Mr Brown

Q —Doctor when we closed just before dinnertime you had started to say—you had stated that you went down to Greenville and opened up a branch there for Mr Burke and that office was going to treat gonorrhea disease and syphilis and then the question was asked you and I don't think it was answered, whether you had put ads in the paper when you opened up that office there advertising the office to treat gonorrhea and syphilis *A* —I can't remember the contents of the ads but I know there was many ads running in the newspapers announcing the opening of the office

Q —And did you practice there in connection with that? *A* —No, sir

Q —Now what kind of a degree or diploma did you get when you say you got three years? *A* —The Bennett College in Chicago and one year at the Eclectic College

Q —And where was that? *A* —At Kansas City, Missouri

Q —And what kind of a degree or diploma did you get from the Eclectic College at Kansas City? *A* —A degree of M D, Doctor of Medicine

Q —Doctor of Medicine? *A* —Yes, sir

Q —Did it state on there whether it was an Eclectic College, or not or an eclectic degree? *A* —That was the name of the university, the Eclectic Medical University that was the name of the school

Q —What does that mean eclectic? *A* —It is a word meaning to select the best I believe that is the literal translation of the word select the best

Q —Isn't it a fact that Arkansas is the only state in the Union now that will issue a license to practice medicine when a man has gotten a diploma from an eclectic college? *A* —I don't know

Q —Do you know of any other state besides Arkansas that will let you practice if you have graduated from an eclectic school? *A* —Oh yes, I think you can go before many medical boards and get a license to practice

Q —Just upon your degree or diploma? *A* —You would have to take the state board examination

Q —Have to take the examination? *A* —Yes sir

Q —Now, when you graduated from the Eclectic College of Kansas City it is a fact, isn't it, that the whole class went at one time down to appear before the Eclectic Board in Arkansas? *A* —I know most of us went down, but I don't know whether all went down or not, I don't think all went

Q —Practically all? *A* —The majority of them did

Q —Did one of the professors go along with them? *A* —Yes, sir

Q —And there they were admitted to practice medicine in the state of Arkansas? *A* —They passed the examination, yes, sir

Q —That examination was before what is known as an Eclectic Board? *A* —Eclectic Medical Examination Board yes, sir

Q —Now, in reference to your licenses to practice medicine I don't think you answered the question as to whether you had a temporary license to practice medicine in California? *A* —Yes sir

Q —And then you applied for a permanent license to practice medicine in California didn't you? *A* —Yes sir

Q —Did you make an application to practice—that was refused? *A* —Yes, sir

Q —Did you make an application to practice medicine in the state of Illinois? *A* —Yes, sir

Q —Was that refused? A —Yes, sir

Q —As late as 1938 isn't it a fact that you again applied to the state of Connecticut to practice in Connecticut? *A* —In 1938?

Q —Yes, sir *A* —No, sir

Q —Within any recent years have you reapplied for a license to practice in Connecticut? *A* —No, sir

Q —My information may be incorrect *A* —You are wrong there

Q —Since your license was revoked in Connecticut you never have reapplied? *A* —No, sir

Q —Lately have you reapplied to any other state to practice medicine? *A* —No sir

Q —When were you first married, please, Doctor? *A* —1907

Mr Morriss Sr —We just say that anything of that kind is incompetent irrelevant and immaterial to any issue in this case, to ask when he was first married and we can see no pertinency of the inquiry here and we shall object to all testimony along that line

THE COURT —I think a general background from the witness and the plaintiff would be admissible

Mr Morriss Sr —We think it would not be admissible on any ground and it is a matter that can't be legitimately used for any purpose, and the only purpose for which it could be used would be an improper one, and therefore, we shall object to it and all testimony pertaining to it

THE COURT —Reference is made to the family in the article that the suit is on I will overrule the objection

Mr Morriss Sr —Note our exception

Q —When were you first married, please? *A* —1907

Q —And who did you marry? *A* —Sally White

Q —Now, when did you marry your present wife? *A* —1913

Q —And what was her name, please? *A* —Minnie Jones, Minnie T Jones

Q —That was in 1913? *A* —Yes, sir

Q —And did you get a divorce from your first wife? *A* —Yes sir, I did

Mr Morriss Jr —We make the same objection to all of that, if your honor please

Q —When was that? *A* —In the early part of 1913

Q —Was that a citation by publication?

THE COURT —Counsel, I don't think there is anything gained in trying out the divorce case

Mr Brown —I am not going to do it, your honor

THE COURT —It is not in issue here I think it is all right to show the constituents of his family and the effect the article might have had on him, but any questions as to the rights or wrongs of the divorce case—I don't know what they are, but I am not going to inquire into that

Q —Did you remarry your present wife? *A* —I did

Q —In what year, please? *A* —In 1915 or 1916, I forget which

Q —Now, your first wife, did she get a divorce from you or did you get a divorce from her—you say she got one from you too

Mr Morriss Sr —That is objected to

THE COURT —What is the materiality of that?

Mr Brown —Just to show the whole picture of it, your honor

THE COURT —Yes, I know, but the picture may be too broad, and take too long and I don t see that we are interested in that, that is not an issue in this article, and outside of showing what the constituents of the family are and who they are, why, I don't think it is material to go into the question of the divorces

Mr Brown —We except to the ruling of the court

Q —Now, when you were down there in Greenville and opened up that office there, weren't you charged with forgery and practicing medicine without a license? *A* —No, sir

Q —Weren't you arrested there for something?

Mr Morriss Sr —We object to that for all of the reasons That is going back to a period, we assume from the inquiry, to 1911

Mr Brown —1913

Mr Morriss Sr —Well, 1911 to 1915, and the Doctor said he had been practicing with irregularity since 1915, and we say it is immaterial and irrelevant and too remote and that it is not the best evidence and that it is of a nature calculated to prejudice his rights without any rule of law which would admit it, and it is not a proper matter of impeachment

THE COURT —I will overrule the objection

Mr Morriss Sr —Note our exception

A —No, sir, I wasn't arrested there I was arrested in Knoxville Tennessee on a charge that was brought down there

Q —What were those charges, please? *A* —I don't know what the charge was, but I know that this fellow, Crawford—

Q —Excuse me, but I understand about that Isn't it a fact that down at Greenville they charged you with forgery and practicing medicine without a license? *A* —Not to my knowledge, I don t even know what the charge was

Q —Did they take you back to Greenville? *A* —I voluntarily went back

Q —Were you in jail there for any time? *A* —No sir, I didn't stay in jail while I was at Greenville, I stayed—

Q —At the sheriff s house, or something? *A* —Yes sir, at the sheriff s house about forty eight hours, and I paid off these bad checks that this fellow had written

Q —And your lawyer's name was Burke? *A* —I don't remember

Q —And the man with you, he was named J E Crawford? *A* —Yes sir

Q —And did your father put up the money for these checks or your father in law?

Mr Morriss Sr —We object to that

THE COURT —I think that is immaterial

Mr Brown —I just had this in mind, it is shown that he is charged with forgery and we just want to show that his family rustled up the money and paid the fellow that had the checks and they never did prosecute the checks, and that is as to why it wasn't concluded with a conviction or otherwise and that is what we had in mind

Mr Morriss Sr —We will ask the court to instruct the jury not to consider the improper remarks of counsel

Mr Brown —I just wanted to tell the court what I had in mind

THE COURT —Yes, sir, but you must not in telling the court attempt to testify yourself until the court has an opportunity to rule on those matters I will sustain the objection to the question as asked and I will instruct the jury to disregard the remarks of counsel as they are not competent

Mr Brown —We except to the ruling of the court

Q —Now, when you were up there in Milford, Kansas did you plead guilty to a liquor case? *A* —I did

Q —Did you pay a fine? *A* —I did

Mr. Morriss Sr —The witness answered before we could make the objection, and we didn't anticipate it We make the same objection as to that

THE COURT —Isn't that charge made in the article?

Mr Morriss Sr —It is not a charge in issue

THE COURT —The entire article is in evidence in the first place, and in the second place the question as to this man's reputation and the damages sustained, if any, by this article that is issued here—all of these matters that tend to show what his history and record are go to make up his reputation, and for that reason it is admissible in evidence and for that reason I will overrule the objection

Mr Morriss Sr —We except to the ruling

Q —Were you arrested up in Kansas for shooting a man or shooting at him, or something of that kind—had a shooting scrape?

Mr Morriss Sr —Same objection

THE COURT —I understand

A —No, sir I didn't get arrested for shooting at a man

Q —You were arrested in some kind of a find or shooting scrape?

Mr Morriss Sr —We make the same objection There is no indication on earth who was right or wrong

THE COURT —Overruled

A —This fellow had me put under a peace bond because I made some remarks concerning him that caused him to be afraid, I guess and they put me under a peace bond, I don't know whether I was arrested or not but I had to give a bond to not shoot him

Q —As to the different specialties that you followed back there in Greenville, North Carolina you were there, as I understand it, working as a doctor in venereal diseases, gonorrhea and syphilis, is that right? *A* —I wasn't working at all, we were just getting the office opened up there and that was the kind of office it was going to be

Q —And then you have advertised that you can treat cancer? *A* —No sir, I haven't advertised that I treat cancer

Q —That you had a cancer cure? *A* —No, sir What you are referring to is some experimental work that I was carrying out

Q —A cure on cancer—a cure for cancer? *A* —Following the line of reasoning of Maud Slye of Chicago

Q —Have you advertised that your treatment that you have given in your practice will benefit cancer? *A* —No, sir

Q—You haven't? *A*—No sir

Q—Do you advertise that your treatment benefits insanity, Doctor? *A*—I haven't advertised in that sense, but I have reported cases of insanity that I have treated that have later recovered

Q—And, then, of course, you have many of these advertisements that your treatments aid in sexual rejuvenation, haven't you, Doctor? *A*—Yes, sir

Q—We went over that this morning? *A*—Yes, sir

Q—Now, your main specialty is the treatment of the prostate gland, is that right? *A*—Yes, sir, the enlarged and infected prostate

Q—Doctor, this prescription 1020 that you treat your patients with, when you sell that prescription how much do you get for it? *A*—I don't sell it in the way you mean it

Q—Well I mean how much does it cost the person that is going to get it that comes to your hospital or that you use it on? *A*—Well, it is not given to an individual separately, but it is always in combination bits, never given separately by itself

Q—If they get it, the patient, it costs them a hundred dollars doesn't it? *A*—That would depend altogether some patients pay us a hundred dollars, but they get different kinds of medicine when they are paying that, and they may get the prescription 1020

Q—I am talking about 1020 *A*—Yes sir

Q—The 1020 prescription *A*—There isn't anybody that comes and pays us a hundred dollars and gets 1020

Q—Six tubes of 1020, don t you sometimes sell that for a hundred dollars? *A*—No sir, that wasn't the way it was handled, we used to treat the infected prostates whenever a man came here to the hospital

Q—I am just asking you now about selling it, and how much did you get for prescription 1020?

Mr Morriss Jr—Counsel interrupts the witness, he asks him a question and then he interrupts the witness before he has time to complete the answer, if your honor please

THE COURT—Let him answer the question However I will admonish the witness to listen carefully and answer the question, and do not answer something else—and you will both save time

Q—Did you ever get any money when you gave a patient 1020, Doctor? *A*—Most assuredly

Q—You did? *A*—Yes sir

Q—How much did you get? *A*—Well, I can't answer you that question

Q—Now, what is in this 1020? *A*—1020 is a number that goes on different ampules that I have in my hospital and the ampules are numbered 1020 and those ampules always contain a certain amount of hydrochloric acid one in a thousand, and the twenties indicate 20 cc of liquid in the ampule, and the hydrochloric acid strength of the ampules is one in a thousand, and that is the reason for the 1020 being on that ampule, some ampules 1020 contain nothing but methylene blue water and hydrochloric acid and other ampules contain hydrochloric acid and coloring matter and some of the iodides, and sometimes a small amount of mercury

Q—You mean that this 1020 has different things in it sometimes? *A*—Yes, sir there are varied forms, the idea of the 1020 is to signify a definite thing

Q—I thought 1020 would be the same thing, but I am so ignorant of such a matter One 1020 will have one thing and another 1020 will have another thing, is that it, Doctor? *A*—Yes, sir, and it is identified by the different colors, and there is 1020 blue and 1020 red and 1020 pink and things like that

Q—What do you put in 1020 blue? *A*—1020 blue is a solution of one in a thousand hydrochloric acid methylene blue and water

Q—How much does that material cost you wholesale? *A*—Oh, those ampules in large quantities five thousand or ten thousand at a time, cost less than a quarter apiece I think about eighteen cents

Q—You mean filled? *A*—Yes, sir

Q—About eighteen cents apiece? *A*—I think so, that is if you buy them in large quantities that is true

Q—Are those ampules that have the 1020 on them are they blue (showing witness instrument)? *A*—I don't know whether it was blue or what it was, I would have to see the color before I could tell you

Q—Those were your ampules? *A*—I don't know whether they were or not

Q—Look at them there *A*—I am looking at them I don't know whether they are my ampules or not

Q—Those labels are yours? *A*—I don't know, I have no way of identifying them the way they are there

Q—You can't tell whether they are yours or not, is that what you mean? *A*—No, sir

Q—Where did you have those labels printed? *A*—The labels that go on the ampules—we have the ampules manufactured in the laboratory at New York, and the manufacturing chemists label them in the laboratory

Q—Is there anything different in the labels that you see on there and used to be on your 1020 ampules? *A*—You know, it has been so long since I looked at one of those labels I don't know

Q—This hasn t got a cork in it but it comes up here with glass and is twisted around and is air tight *A*—Yes, sir, and if you want to get it out you have to break the top

Q—You have to break the top? *A*—Yes sir

Q—Now, what do you do with the 1020 blue when you give it to a patient? And how does he take it inside of the body how do you get it into his body? *A*—It is given into a vein

Q—You inject it into a vein? *A*—Yes sir

Q—You don t inject it into a muscle? *A*—No sir

Q—After you inject it into the vein what effect does it have on the patient? *A*—It increases the number of white blood cells

Q—Now, is this 1020 blue that you speak of, is that isotonic? *A*—I don t know whether it is or not

Q—Do you know what isotonic means? *A*—It escapes my mind for a moment, I don t grasp the meaning of it

Q—You don t know what isotonic means? *A*—It escapes me for the moment

Q—Do you know what hypertonic means? *A*—I can't frame a definition in my mind, no

Q—Would you read this please (handing the witness instrument), this is a piece that appeared in the Bureau of Investigation pamphlet of the American Medical Association a laboratory report, and see if that is a correct analysis of your 1020? *A*—Well I don't see anything in here saying anything about the presence of hydrochloric acid

Q—Well, you can turn it over there, it turns over, I believe Yes, sir, there it is (indicating) *A*—My solution contains methylene blue and hydrochloric acid, and I don't see that this says anything about the hydrochloric acid being in there

Q—All right now, you heard Dr Peterson yesterday describe in detail the way you performed the operation at the present time—it is Dr Petermeyer, I beg your pardon *A*—Yes sir

Q—You listened to that description? *A*—Yes, sir

Q—Was it correct, his description of the operation correct? *A*—In a general way, yes, sir

Q—How would you add to it or how do you want to change it? *A*—I would let it stand as it is If I was describing the operation, why, naturally, my description would be a little different

Q—I don t want to take the time— *A*—I will accept his explanation as satisfactory in order to stay out of all of that rehashing

Q—Now, tell us, please does a little goat gland have little nerves there when you take a little testicle out of a young goat, does it have nerves before it is taken out? *A*—Naturally, any living organism in an animal body has nerves and blood vessels

Q—Now explain to us, please, how you could make that little testicle of a little—how old were the goats ordinarily? *A*—About three weeks

Q—That little testicle of a young goat, you claim that that lived and grew after you implanted it in a human testicle? *A*—Some of them seemed to grow and enlarge and others, the majority of them, went through a process of absorption

Q—Absorption? *A*—Yes, sir, they were gradually absorbed

Q—How long did it take to absorb? *A*—I examined patients following the transplantation of them and some of them are gone in three months and some in six months, and I have seen evidence of remnants of them after even one and two years

Q—*You mean to say that little thing lived and was just like a part of* the human testicle and it was living in there after you put it in there? *A*—No, sir, I don't conceive of it that way, I don t conceive of it as being a part of the human testicle

Q—Why wouldn't it just get rotten in there? *A*—If it became infected it would, it would spoil

Q—Well, if you put that little piece of meat in there and it is not getting any blood or anything just laying in there— *A*—You see, the patient s blood naturally bleeds into the little pocket where the gland is placed

Q—Where is it coming from if there isn't a hole in the blood vessel of the human for it to get out? *A*—The gland itself is a sponge like tissue, just like a piece of sponge, and whenever you drop it in a patient where there is an open wound it immediately becomes filled with the blood from the patient, just like a sponge becomes filled with water from a drop of water

Q—You don't claim you connected up the nerves or any blood vessels? *A*—Oh, Lord, no

Q—You just took this little thing separate and put it in that slit in the testicle and sewed it up? *A*—Yes, sir

Q—And the blood in the body of that testicle would squeeze in there to keep that thing alive so it wouldn't rot in there, is that the idea—I may express it very crudely *A*—Naturally when that foreign matter was placed inside the patient's body it was surrounded by the patient s blood vessels, and that would be the first thing that would happen and the blood vessel—I mean the patient's white corpuscles would naturally rush in and in the process of inflammation that would be set up in there in some of these patients there would be a substance like a sac that would really form around this gland, I have opened them up later and seen them where it looked like nature herself had tried to put a capsule around this gland

Q—Now, Doctor, just a question aside here Now, up there in your country hospital, up there in Arkansas, the one out in the country, who now receives the patients there at the hospital, the doctor that admits them into the hospital? *A*—Dr Purcell

Q—How do you spell that? *A*—P u r c e l l

Q—Now, in your advertisements or talks do you tell the patients or the public that you treat prostate glands without surgery? *A*—No, sir

Q—You tell them you treat it without removing the prostate? *A*—Yes, sir, that is it yes, sir

Q—This part of your operation is that you take a tube and an electric needle and put it up there, and that is the surgery that cuts a part of the prostate off, isn t it? *A*—Yes, sir, trims off part of the prostate

Q—Just briefly, without describing the operation, what do you claim is the effect—take a man that is suffering with prostate trouble and you operate on him with the usual and normal operation, what do you claim is the effect of that operation? *A*—The prostate gland is reduced in size

Q—What is the effect that it has on the man? *A*—The man feels better and he becomes more energetic and he gains weight and his appetite becomes better and his outlook on life is better

Q—Does it have any effect on his sexual powers? *A*—Many of the patients say it has a good effect and the sexual powers are increased, yes sir

Q—Sometimes does the patient, after he leaves you, for a post operative treatment and he goes home, does he take along with him some of the tubes of 1020? *A*—No sir, we don t permit that, and we haven t in several years

Q—You used to do that? *A*—Several years ago we did but we do not do that any more

Q—Well now, when the patient took this 1020, when you used to let him take it home and let his own doctor treat him with it these six tubes how much did you charge him for it? *A*—We wouldn t charge him anything for that, sometimes the man had to go home before he could complete the amount that we wanted to give him, so we would send the supply home with him so his physician could complete the treatment

Q—Didn't Dr Petermeyer state that yesterday? *A*—Dr Petermeyer was confused there, we don t charge any patients a hundred dollars and we don t send any medicine to be given hypodermically or intravenously to any patient

Q—I notice on one piece of literature it say 'J R Brinkley, M D,' and what is that M D? *A*—Doctor of Medicine

Q—It says C M, and what is that? *A*—Master of Surgery

Q—Then it says Dr P H *A*—That is Doctor of Public Health

Q—Sc D *A*—Doctor of Science

Q—And then "Chief Surgeon" Now, where did you get all of those degrees from? *A*—Well, on this diploma I have, it says "Doctor of Medicine and Master of Surgery," and that entitles you to say M D and C M if you care to, the Doctor of Science degree was conferred on me by the Chicago Law School, an honorary degree and the Doctor of Public Health was conferred on me by the Eclectic Medical University of Kansas City, Missouri where I received my M D degree

Q.—Who was that that conferred the Doctor of Science? *A.*—The Chicago Law School, Chicago School of Law.

Q.—So, it was the Chicago Law School? *A.*—Yes, sir.

Q.—Do you also put on your names sometimes LL.D.? *A.*—I will declare, I don't know.

Q.—Do you ever claim you have had a degree of LL.D.? *A.*—I don't remember.

Mr. Brown:—That is all the questions we care to ask.

Mr. Morriss Sr.:—We expect to put him on later, but we will not ask any questions now, Your Honor.

THE COURT:—All right.

Witness excused.

Mr. Reynolds:—Your Honor, at this time we would like to introduce a few exhibits, marked Exhibits 39, 40, 41 and 42, inclusive. (Handing instruments to counsel for plaintiff.) While those exhibits are being inspected, we are going to offer these in evidence, it being the marriage license of John R. Brinkley—well, if you wish to inspect those first, (handing instruments to counsel for plaintiff).

Mr. Brown:—Excuse me, Your Honor, but there was a matter that I overlooked to ask Dr. Brinkley.

THE COURT:—Do you want him to resume the stand?

Mr. Brown:—Yes, sir.

THE COURT:—All right.

Dr. John R. Brinkley, recalled as a witness for further cross examination, having been previously duly sworn, testified as follows, to wit:

FURTHER CROSS EXAMINATION

Questions by Mr. Brown:

Q.—Doctor, did you write these letters? (Handing witness instruments.) *A.*—Yes, sir, those letters were written by me.

Mr. Brown:—I offer the letters in evidence (Exhibits 43, 44 and 45).

THE COURT:—What is your objection to this, Counsel?

Mr. Morriss Sr.:—To these and the others, Your Honor, there are quite a number of different documents and there are various different objections to them, and we don't want to encroach upon the rule of discussion of the matter in the presence of the jury, and it brings up the question of some matters about which it will be necessary to put on some evidence.

THE COURT:—Particularly, what are the grounds, without the argument? There is a difference between making the argument and just giving the technical objection.

Mr. Morriss Sr.:—I shall show that the letter of February 8, 1935, is a privileged communication, and that, among others, is the objection. Then, as to all of them that they are immaterial and irrelevant to any issue, and they relate to a wholly different collateral matter not involved in any way in this proceeding, and they are incompetent to establish any issue or any defense in this case.

THE COURT:—All right, I will hear from the other side. I will ask Counsel, without testifying in any way or without attempting to state the contents of these things, to tell me why you think they are admissible.

Mr. Brown:—Your Honor, there is one part that is alleged on here by the plaintiff as to the effect that the doctor continues to make money, not withstanding the efforts of the various governmental departments and agencies, and there is another portion of the article declared on which says he is still on the air in spite of many efforts to remove him from the air, and these letters are written by Dr. Brinkley to the radio station.

Q.—Dr. Brinkley, was Mr. Burke your attorney? *A.*—Yes, sir.

Q.—And did you have a contract and have some business with Radio Station KFEG in St. Joseph, Missouri? *A.*—Yes, sir, I was broadcasting over it by remote control.

At this point there was considerable discussion over the introduction of pamphlets, documents and evidence relative to various incidents which were associated with the career of Dr. Brinkley and as to the possibility of the introduction of such materials.

EVIDENCE OF JACK K. TINGLE

Jack K. Tingle, official court reporter from Dallas, Texas, introduced in evidence copies of broadcasts made by Dr. Brinkley from his station in Mexico in 1931.

TESTIMONY OF DR. EUGENE W. SCHOEFFEL

Dr. Eugene W. Schoeffel, chemist employed by the American Medical Association, testified as to his examination of the contents of ampules sent to the American Medical Association by physicians who had obtained them from patients of John R. Brinkley.

The evidence proceeded:

Q.—Now, Doctor, will you tell us what you determined from your analysis to be the contents of these ampules.

Mr. Morriss Jr.:—The Court notes that our objection goes to all of this.

THE COURT:—All right.

A.—First the material was measured out.

Q.—Just a minute, Doctor, don't tell me how it was all done, but tell the jury what your conclusions were, what your findings were after all of these tests were made, the stuff that was in it, that is what we want to know. *A.*—You want to have the conclusion of the tests?

Q.—That is right. *A.*—The conclusion was placed down that this ampule contained approximately 20 cc. of a bluish- sapphire-like liquid, which had a density—I will have to quote,—

THE COURT:—You may refresh your memory, and I told you that, but you must not read it to the jury, but you can refresh your memory and then testify.

A.—Which had a specific gravity of 0.9985 in respect to water, and at 25 degree solution, 0.9971.

Q.—What do you mean by that last statement, just in ordinary language so everybody can understand it. *A.*—By specific gravity is meant the weight of a measured solution at a certain temperature.

Q.—And does your statement mean that it is about the same as wate as to what you found as regards this specific gravity? *A.*—Somethin like it, very close to distilled water.

Q.—What else was found? *A.*—It was also found that the color o the solution is of the indigo type.

Q.—Will you explain just briefly why you use that term "indigo type"? *A.*—The color chemist knows approximately over 2,000 different blue colors.

Q.—And the indigo type? *A.*—The indigo type is a certain chemical formula by which various shades and hues of blue color can be made.

Q.—Is that the same coloring substance as one gets from methylene blue? *A.*—No, sir, it wouldn't be methylene blue, this is a different color type.

Q.—All right, now, what else was found? *A.*—Besides that, the spectroscopic analysis indicated the presence of several metal elements; however, these elements were found in traces only.

Q.—What do you mean by saying they were found in traces only? *A.*—From one of the tests we found that the solution contained approximately 0.004 of a per cent of dry material.

Q.—0.004? *A.*—0.004.

Q.—Is that in connection with these 20 cc. of material you say were in here after you had obtained that dry material in whatever process you used—could you see it with your own eyes? *A.*—It is an exceedingly small amount.

Q.—And what else was found? *A.*—Besides which we made tests for halogen, and that is the term for chlorine, iodine, fluorene and bromine.

Q.—What did you find? *A.*—0.2 cc. of the solution was tested with 1 cc. of diluted nitric acid and 1 cc. of silver nitrate test solution, and no detectable traces of chlorine could be found.

Q.—With that finding is it possible there was any hydrochloric acid in this solution, or not? *A.*—There is a remote possibility that chlorine could have been present if the entire 20 cc. would have been used.

Q.—And if chlorine were present that would mean hydrochloric acid, would it? *A.*—Not directly.

Q.—It might mean that? *A.*—It might mean.

Q.—From the sum of all of your tests were you able to determine whether or not, and have you a finding as to whether or not there was any hydrochloric acid in this solution? *A.*—I only can say that the tests produced on 0.2 cc. didn't give us a detectable trace of chlorine; however, it is known that a specialty ampule glass under certain conditions gives off traces of chlorine.

Q.—All right, now, Doctor, in making your analysis you spoke about finding dry substances, dry matters, dry materials, and how did you get that from this as it originally appeared? *A.*—The material was dried down in a platinum dish over a waterbath.

Q.—That is the same as boiling? *A.*—Boiling down.

Q.—And how large a speck did you find of dry material, the size of the head of a pin or the size of a pin point, or what—something we can understand. *A.*—Say, the point of a pin.

Q.—And it was from that dry material that all of your subsequent analysis was made. Is that right? *A.*—Yes, sir, after the acidity of the solution was stated.

Q.—What else did you find in the dry materials, if anything? *A.*—I have to refer back (looking at paper); the amount of hydrogen concentration we found to be of a very weak solution, and this led us to believe—

Mr. Morriss Sr.:—We object to what they would believe, Your Honor.

Mr. Reynolds:—I think he is going to—

THE COURT:—He can say what he believed himself, but he couldn't speak for anybody else. He used the term "us," and I don't know what he is talking about.

Q.—You made this analysis yourself, and that is what you are talking about? *A.*—Yes, sir, I do.

Q.—Well, what was it that you actually found, now, without regard to what you believed, at the time when you completed another test, just say what was it you found—I want to know what was in that pinpoint of matter.

THE COURT:—It seems to me the way you develop this is highly technical.

Mr. Reynolds:—It is very difficult.

THE COURT:—I don't know whether it is or not. State the technical proposition in order to get it into the record and then ask in terms of a, b and c what he is talking about. You asked Dr. Brinkley, or co-counsel did, and he said he had methylene blue and a little hydrochloric acid in it and outside of that it was water; now, you can take one of these chemists, one of these ten chemists, and he could probably talk to us about that for a week, take a little pinpoint of solid matter and break it down and talk about it a long time and nobody would understand it, and you are not getting anywhere.

Q.—The last question is to tell us, just enumerate the substances you found in that little point of a pin of matter, if you haven't named them all. *A.*—Traces of metallic elements, approximately 0.003 of a per cent of indigo type dye, and most of the indigo type dyes contain a small, practically immeasurable amount of sodium chloride, and the ampules also give off sodium chloride.

Q.—Did you find this substance to be an isotonic substance? *A.*—No, sir, the substance wasn't isotonic.

Q.—Will you explain to the jury, so that we can understand it, what we mean by isotonic? *A.*—Isotonic is understood to be a solution which is comparable with a 0.9 per cent sodium chloride solution, and it is generally called a physiological salt solution, and if the solution is below the content of 0.9 sodium chloride, the solution is called hypotonic, and if it is above 0.9 per cent sodium chloride it is called hypertonic.

THE COURT:—Now, wait a minute. The province of the Court in presiding over the trial is to proceed in order to get something out of it, and you asked him to explain that so we could understand it, and, after all, I suppose the purpose of putting the witness on was to find what he found in the ampules and say it so somebody besides a chemist can understand it, and if the ampule had medicine or chemical properties that had some significance, let him say so, and if it was nothing but colored water, let him say so, but a man can talk about H_2O and he may know what it is, but the general public wouldn't know it is water; so, let's talk in the terms of the Court and the Jury.

Mr. Reynolds:—He can't go into the therapeutic effects because it takes a doctor to do that, and we will tie that up later.

The cross examination brought out the fact that the ampules had been handed to the witness by Dr. P. N. Leech, director of the laboratory of the American Medical Association.

SATURDAY, MAY 13, 1939

THE WAGNER NATIONAL HEALTH BILL

In the Organization Section of this issue of THE JOURNAL appear statements of hearings held before the Senate Committee on Education and Labor last week, before which appeared Senator Wagner himself, Miss Josephine Roche and later Dr. Arthur W. Booth, representing the Board of Trustees of the American Medical Association. Previously representatives of many farm agencies had appeared before the Senate committee urging legislation to increase federal expenditure for health. At a subsequent date representatives of some of the various state medical societies will appear before the Senate committee, as will also a group of representatives of the American Medical Association.

Easily apparent thus far is the failure of the Interdepartmental Committee to Coordinate Health and Welfare Activities to be influenced to any considerable extent by the various agencies which appointed committees to consult with the committee. When the President of the United States sent the National Health Program to the Congress in January, recommending careful study rather than enactment, it was apparent that the National Health Program had not been modified in any appreciable manner as a result of such hearings. Moreover, in her statement before the Senate committee last week Miss Roche again emphasized the assertion that the statistics in the National Health Survey had not been challenged, notwithstanding the fact that in THE JOURNAL, as well as in many other publications, such challenges have been made. Especially notable, of course, are the considerations of the American Hospital Association and the Catholic Hospital Association, which certainly have challenged some of the statements relative to the needs in the hospital field. Indeed, the most significant challenge yet made appears in the words of Alphonse M. Schwitalla, S.J., who says "If all this is social security, if all this is necessary for the preservation of the national health, then justly a philosophy of health care must be restated, and medical practice and hospital practice as today understood must be razed to give way to overpowering structures of huge bureaus, national councils and state organizations founded not upon Christian inspiration but upon legal enactment." If any further challenge is needed, readers of THE JOURNAL are referred especially to the general statement presented by Dr. Arthur W. Booth, Chairman of the Board of Trustees, which appears on page 1972 of this issue.

The representatives of the American Medical Association who will appear before the Senate committee at a later date will present facts and documents which controvert absolutely some of the statistics and data on which many of the recommendations in the Wagner National Health Bill are based. The medical profession will do well to bear in mind that the House of Delegates of the American Medical Association at the session to take place in St. Louis next week no doubt will express clearly the point of view of the American Medical Association in this proposed legislation.

THE CALL FOR THE PHARMACOPEIAL CONVENTION OF 1940

The President of the U. S. Pharmacopeial Convention is authorized to issue a call for the decennial meeting on May 1 of the year preceding the meeting. By this time various medical societies and medical colleges, as well as various pharmaceutic groups, should have received the call and the request to send delegates. Before the Pharmacopeial Convention of 1930 the Council on Pharmacy and Chemistry[1] urged all organizations, medical, pharmaceutic, chemical and others, carefully to select delegates noted for high ideals, for breadth of vision and for sound judgment as well as for technical knowledge. The aims and purposes of the Pharmacopeia were admirably expressed by its principal founder, Lyman Spaulding, M.D., in the preface to the first edition.

In its editorial of ten years ago THE JOURNAL stated:

> Although federal laws concerned with the control of the purity of drugs provide for the enforcement of drug standards set forth by the Pharmacopeia, the book is not published by or under the control of the federal government. It is published by authority of the United States Pharmacopeial Convention. This body is composed of members who are sent as delegates by national or state associations of physicians, pharmacists and other groups concerned with medicine and drugs, by schools of medicine and of pharmacy, and by certain government services. The convention meets once every ten years, and its chief function is the selection of the Committee of Revision of the United States Pharmacopeia. To this committee is assigned the task of making any desired changes in the Pharmacopeia then in force and of issuing a revised edition of the book. The next Pharmacopeial Convention has been called for May 13, 1930, at which time the delegates appointed by the constituent bodies will meet in Washington, D. C., and inaugurate the preparation of the next, the eleventh, revision of the United States Pharmacopeia.

The convention of 1930 was in many respects unsatisfactory because its conduct was undemocratic and

1. The Call for the Appointment of Delegates to the United States Pharmacopeial Convention, J. A. M. A. 93:989 (Sept. 28) 1929.

unscientific. Astute and industrious interests overwhelmed the convention with their representatives. Fortunately, the Board of Trustees of the U. S. Pharmacopeia, the chairman and his helpers on the Revision Committee were able to carry out their work efficiently. As a result, the Pharmacopeia of 1930, which became official in 1936, was much better than might have been anticipated but it was produced without some assistance which might otherwise have been secured.

The entire method of developing the Pharmacopeial Convention requires radical revision. At present any organization entitled to representation may send three delegates. Medical organizations, unfortunately, do not feel in a position to pay the expenses of three delegates. Some schools of pharmacy and pharmaceutic organizations have full representation because commercial interests are willing to see that delegates participate in the convention. Thus in 1930 medical delegates were outvoted by this arrangement.

When the Pharmacopeia was first devised, distances were great and communications were difficult. It was therefore provided that no one could be a member of the Revision Committee unless he attended the Pharmacopeial Convention. The Revision Committee of 1930 was deprived of the services of many good men, had they been willing to serve, on no other ground than that they had not attended this haphazard, ill conducted convention. Medicine has asked either that it be given equal representation on the Revision Committee or that, as it requested in 1930, it be given one third representation, with the understanding that therapeutic scope shall be controlled entirely by the medical group and that questions of pharmaceutic necessity be decided by the pharmaceutic group. This was denied. If the cooperation of the medical profession is to continue, some effort must be made to meet the reasonable demands set forth in 1930.

In various meetings of the Council on Pharmacy and Chemistry, the Board of Trustees, and other bodies of physicians, the following principles have been formulated: To correct the evils of one-sided representation it would seem that only one vote should be accorded an organization. This would preclude the practice by some pharmaceutic interests of securing credentials from various organizations or schools and selecting delegates who will vote as they request in the convention. The rules should be corrected so that the most capable men in the country may serve on the Revision Committee, and the prerequisite that a man must attend the convention to serve on the committee should be removed. Until these amendments are made there should be restored the agreement of the 1920 Pharmacopeial Convention that medical men shall control therapeutic scope and pharmaceutic men shall control pharmaceutic scope.

During the past five years progressive leaders in the pharmaceutic field have shown commendable effort in trying to work out some method whereby a reasonable scheme of cooperation with physicians may be established. The Board of Trustees of the U. S. Pharmacopeia met recently with the Board of Trustees of the American Medical Association to discuss means of cooperation. Many physicians believe that the time has come when the Pharmacopeial Convention must decide on the general principles that have been mentioned before they will commit themselves to full participation on the various committees of revision. The medical profession has shown its desire to be cooperative. THE JOURNAL has published during the last year a series of articles on "The Pharmacopeia and the Physician." These articles were published at the request of the Pharmacopeia authorities and they have been received with much favor by both the medical and pharmaceutic professions. To the Pharmacopeial Convention of 1940 only those delegates, medical or pharmaceutic, should be sent who will come with broad-minded attitudes and with the serious wish to work harmoniously toward constructive policies.

Current Comment

SEX HORMONES HOLD THE STAGE

Today the desks of physicians are being flooded again with fantastic advertising claims for sex hormones. New heights have been reached with the publication of two pamphlets, "Perandren" (Ciba) and "Roche Review" (Roche-Organon). The recommendations reveal a policy with little regard for scientific evidence. The name of one of the Roche-Organon preparations, Neo-Hombreol (presumably new manhood oil), is significantly reminiscent of "Lost Manhood" exploitation. And most of the claims are apparently based on one or two experiences in which the reporter has neglected to discount for the power of suggestion. Ciba naively advises testosterone propionate for therapy on the basis of admitted "bits of evidence, published and unpublished." "Atonicity" and "mammary gland pathologies" are among the firm's recommended indications for androgenic therapy. But this is conservatism itself when compared to the opus of the "scientific staff" of Roche-Organon, who have prepared a chart and "dosage schedule" for sex hormones. Here are indications, dosage and everything except references to scientific literature urging androgenic therapy for many conditions, including epispadias, hypospadias (conditions which always have required and always will require surgery) and Graves' disease in women. Estrogenic therapy is prescribed for acne, alopecia, impetigo, Buerger's disease, iridocyclitis, polyarthritis and many another condition. And in the following effusion Mr. Elmer Bobst really "goes to town."

Dear Doctor:

No DOUBT young Juan was greatly admired by all the young ladies of Servas as he matured, for he was a fine looking lad, with a splendid physique and possessed a daring personality. His adventuresome spirit forced him at a very early age to

take a hand in the Moorish Wars, and he was only 33 years old when it led him again to persuade Columbus to let him go along on his second trip to the new world. But by the time the estimable Juan had conquered the Island of Porto Rico and had settled down to the rather soft and engaging life of its Governor, the first shadow of old age started to fall across his pathway. As his vigor began to wane, the Indian legends about the Land of Bimini and its wonderful spring of waters with their marvelous curative powers intrigued him more and more. And soon thereafter Juan Ponce de Leon—for it was none other than the famous Ponce de Leon—set forth on his memorable search for the so-called Fountain of Youth. When Ponce de Leon began his quest of the youth-restoring waters, he was just about fifty years of age. Yes, just about the period of man's life when the downhill journey becomes significant. Is it due to the rapid decrease of the male sex hormone secretion at middle life? More and more physiologists and endocrinologists are coming to that conclusion. A study of the clinical characteristics of the male climacteric, embracing physical, psychological, and functional changes, leads rather definitely to the conclusion that proper administration of testosterone propionate can play the same replacement role in man as does estrogen therapy in the menopause, or female climacteric. Testosterone propionate, which we are making available under the name of Neo-Hombreol, is the active, chemically pure, crystalline propionate salt of the male sex hormone, identical in every respect with the same substance derived from natural sources and with the added advantage of synthetic production. We suggest the experimental use of Neo-Hombreol for combating the annoying symptoms of the male climacteric. Treatment should be started with injections of Neo-Hombreol. For maintenance purpose we then suggest the use of Neo-Hombreol Ointment which is now available in a most accurate dosage form called the Dosule. We will gladly send you a 3-day supply of Neo-Hombreol Dosules if you will make use of the enclosed card.

Sincerely yours,

Elmer H. Bobst,
President.

This flamboyant exploitation obviously presupposes an extraordinary degree of ignorance on the part of the physician. It can do little more than delay the scientific use of these compounds, meanwhile classifying the concerns responsible with others who sponsor reckless claims. The report of the Council on Pharmacy and Chemistry on the Present Status of Testosterone Propionate and on rejection of Perandren, Oreton and Neo-Hombreol appears in this issue of THE JOURNAL, page 1949.

SULFANILAMIDE AND SMALLPOX

Elsewhere in this issue (page 1936) is a report of the treatment of four cases of smallpox with sulfanilamide. In three there was only an evanescent macular eruption which rapidly disappeared, and in the remaining case there were only three pustules. Three additional patients observed about the same time were treated only symptomatically and in all three the typical eruption of smallpox developed. All treated and untreated patients recovered. This interesting observation seems to indicate that sulfanilamide, when given early in the disease, has a beneficial effect on the cutaneous lesions and possibly on the disease itself. Although smallpox is increasing (there were 14,355 cases reported for the year 1938) the disease is now mild, as evidenced by only thirty-five deaths in 1936 out of 7,459 cases in that year. In the presence of such a low case fatality rate, conclusions as to the value of sulfanilamide in preventing mortality from smallpox cannot be drawn from the four cases thus treated.

ABSORBABILITY OF CATGUT

Two recent studies on the absorption of catgut are of much practical importance to surgery. Bates [1] made experiments on adult dogs, using various sizes and types of catgut. After varying intervals it was found that plain catgut excites a prompt and violent exudative foreign body reaction which delays the appearance of fibroblasts and therefore delays wound healing. Large, plain catgut however was absorbed about as fast as the smaller sizes, but no size held throughout the time during which wound support is needed. Chromic catgut was associated with a retarded and lessened exudative foreign body reaction and with the early appearance of fibroblasts and early healing. Further, Bates found that small chromic catgut functions longer than large chromic catgut and that wound support and healing were most satisfactory when the smallest chromic suture was employed. In experiments on human beings, Wolff and Priestley [2] reported tests of the rate of absorption of various types of catgut. On closure of the incision in an unselected series of abdominal operations an interrupted suture of the catgut to be tested was placed through the anterior fascia of the rectus muscle and tied round a loop of nonabsorbable suture material which was permitted to project from the skin. Gentle traction was made on the projecting suture material every day or two after operation until it came out, thus indicating that the catgut was absorbed. In many cases three and four of these test sutures were used simultaneously. Three hundred and fifty-eight strands of catgut were tested on 164 patients. It was found that small sizes of catgut remained unabsorbed as long as or longer than larger sizes. The average absorption time of 000 chromic catgut in one series of patients was fifteen days. In contrast, strands of chromic catgut 1 and 2 of the same brand were absorbed in the average time of 10.6 days. Single strands of catgut lasted as long as double strands. It might be concluded, therefore, that the only advantage in the use of double strands is to secure greater initial tensile strength. In certain cases chromic catgut was absorbed as fast as or faster than plain catgut, although as a rule the process of chromicizing catgut materially lengthens the time necessary for its absorption. Great individual variations in absorption time were found, the greatest when chromicized catgut was used. These investigators further concluded that labels which indicate the length of time necessary for absorption of catgut are entirely fallacious as far as the human being is concerned, that drainage and suppurating wounds do not cause early absorption of catgut, and that certain brands of catgut consistently last longer than other brands. The practical applications of these newer studies of the absorbability of catgut deserve early confirmation and wide attention.

ORGANIZATION SECTION

HEARINGS ON SENATE BILL 1620, THE SO-CALLED WAGNER NATIONAL HEALTH BILL

On May 4, 1939, Senator Robert F. Wagner appeared before the Senate Committee on Education and Labor to present a statement on the National Health Bill. Briefly, Senator Wagner called attention to previous legislation for health, including the Sheppard-Towner Act, the Social Security Act and the legislation establishing the National Cancer Institute. He pointed out that the President had sent the National Health Program with its considerations to Congress for further study.

Senator Wagner pointed out that the costs of medical care have increased as our resources of medical skill, facilities and personnel have advanced, but that inequalities in the distribution of medical care have been widened. He also said that the National Health Bill was drafted in response to a plea from the people that our government take health from the list of luxuries to be bought only for money and added to the list containing the inalienable rights of every citizen.

Mr. Wagner stated that there is no intention to put the federal government into the business of furnishing medical care and that on all the phases of the bill the initiative will rest with the states. Further, that federal encouragement and cooperation will be effected through the traditional method of grants in aid. He then explained the various phases of the bill. In association with preventive measures is a new program, under title XIII, to enable the states to extend and improve existing provisions for the care of the sick and the treatment of disease. He said: "The Social Security Board, which is charged with the administration of this title, is not authorized to give or withhold grants at pleasure, or to require state plans to develop along any predetermined lines. I have said again and again that nothing in the bill requires the states to establish compulsory health insurance. Within the limits of certain necessary standards, the states are free to provide programs of medical care compatible with the needs and desires of their own people, and made effective through methods of their own choice. The state plan may apply merely to people on relief or extend to others higher in the economic scale. It may be financed by general taxation, by the contributions of the beneficiaries of the medical services, or by combinations of these methods. The scope of medical services and the manner of their provision will be for the individual state to decide, so long as the program is statewide or becomes such within five years, involves financial participation by the state, and complies with other standards prescribed by the bill."

Senator Wagner said that the bill does not propose to flood the country with hospitals and health centers, and that no money would be advanced until the submission of a careful state plan. He also defended the reorganization which places the United States Public Health Service under the Social Security administration with the following statement:

"The plan of reorganization recently submitted by the President properly conceives of health protection as an integral part of our efforts toward human security. By placing both the Social Security Board and the Public Health Service in the new Federal Security Agency, the reorganization plan establishes a sound nucleus for the coordination of federal health functions which is so essential to the efficient operation of a national health program."

It was his concept that the exactment of this program would result in the practice of economy, since sickness is responsible for one third of all dependence on public relief or private charity.

"In closing," he said, "I want to pay deserving tribute to the unselfish spirit, enterprise and generosity of the members of the medical profession for the splendid and self-sacrificing labors in alleviating sickness and promoting the people's health. A major purpose of this legislation is to help them to carry more effectively a burden which they have long carried alone. Both in the consideration of the bill and in its administration upon enactment, we bespeak, and we know we will have, the support and cooperation of the members of the noble profession which 'has for its prime object the service it can render to humanity.'"

STATEMENT BY JOSEPHINE ROCHE

Miss Josephine Roche, in her appearance before the Senate Committee on Education and Labor, recapitulated the development of the National Health Program and told the story of the National Health Conference. She emphasized also the deficiency of medical care among the poor and among people with small income, and some of the other statements made in the National Health Survey. In her statement on the National Health Conference she said "At the end of the first day's session, one of the participants asked the question 'Are there any members of this conference who seriously challenge the statements with reference to need which were made this morning?' This question was stated to the conference by the presiding officer. There were no challenges then and there have been none since." Obviously all readers of THE JOURNAL know that the figures of the National Health Survey as to medical care have been repeatedly challenged in many ways by many different agencies.

Miss Roche then proceeded to outline the National Health Program as developed by the Interdepartmental Committee to Coordinate Health and Welfare Activities of the United States government. She then pointed out that her committee did not recommend state medicine or a federally administered system of compulsory health insurance but that it did recommend the assistance of grants in aid. She stated that nineteen groups had met with her committee following the National Health Conference and that these groups were essentially in agreement as to the need for action and, "so far as there were any differences of opinion among some of these groups, they differed only as to how far and how fast such action should proceed." In her conclusion she said:

"May I emphasize that the committee's recommendations are not aimed merely at conditions as they exist today but, in the words of the President of the United States to the National Health Conference, 'we have before us a comprehensive, long-range program, providing for the most efficient cooperation of federal, state and local governments, voluntary agencies, professional groups, mediums of public information and individual citizens.' The committee does not visualize that it is practicable to put into effect immediately the maximum recommendations. It contemplates expansion along well planned lines with a view to achieving operation on a full scale within ten years. However great the difficulties, it must be realized that we shall learn only by doing. The committee therefore feels very strongly that the time has come to make a decision on a national health policy and a beginning on a national health program.

"The bill introduced by Senator Wagner, S. 1620, now under consideration by the Senate Committee on Education and Labor, would translate into reality the recommendations of the Interdepartmental Committee. In view of the importance of the nation's human resources, I trust that this legislation may be given serious and prompt consideration."

STATEMENT OF DR. ARTHUR W. BOOTH, CHAIRMAN OF THE BOARD OF TRUSTEES OF THE AMERICAN MEDICAL ASSOCIATION

On May 5, Dr. Arthur W. Booth, chairman of the Board of the Trustees of the American Medical Association, appeared in behalf of the Association and made the following statements:

I thank the committee for this opportunity to state the position of the American Medical Association with respect to some of the proposals set forth in the pending bill, S. 1620, and for the opportunity to be given later to introduce evidence in support of the Association's position. In order that the committee may better appraise what I say and the evidence to be presented hereafter by the Association, I submit for the record a memorandum showing briefly what the American Medical Association is and what its objectives are. Such information is particularly needed just now because of attacks on the Association, some made in good faith and some made apparently because of selfish interests.

It is sufficient at the present moment to say that the American Medical Association is a federation of state medical asso-

ciations. It is governed by a House of Delegates, made up of 154 delegates elected by the state medical associations of which the American Medical Association is composed; fifteen elected by the several sections into which the Scientific Assembly of the Association is divided, each devoted to a particular branch of medicine, such as surgery, obstetrics and internal medicine; and three appointed, one each by the Surgeon General of the Army, of the Navy and of the Public Health Service from the commissioned medical corps of those services. Of the 173,879 physicians lawfully authorized to practice medicine in the United States, 113,113 were on May 1 of this year members of the Association.

The House of Delegates of the American Medical Association fixes the policies of the organization. The House has not met, however, since the bill now under consideration was introduced. It will assemble on May 15 in St. Louis and will consider the bill, and representatives of the Association will report to your committee as promptly as practicable whatever action the House takes. They will lay before you, too, some of the many data that the Association has assembled during recent years, relative to the economics of medical service from the standpoint of the physician, of the hospital and of the people.

Although the House of Delegates has not had an opportunity to consider the pending bill, it did consider, at a special session in September last, the so-called National Health Program formulated by what is sometimes referred to as "The Technical Committee on Medical Care." This Technical Committee, it should be understood, was created by a committee appointed by the President and known as "The Interdepartmental Committee to Coordinate Health and Welfare Activities." The report of the Interdepartmental Committee to the President, including the report of its Technical Committee, was submitted to the Congress by the President [See H. R. Doc. 120, 76th Congress, 1st session], and S. 1620 proposes to make the recommendations of the Interdepartmental Committee, or some of them, effective. The conclusions of the House of Delegates of the American Medical Association, at its special session in September last, based on the report of the Technical Committee, are therefore relevant to the pending bill and to the deliberations of your committee, so far as the bill is founded on that report.

Judged by the principles laid down in the resolutions of the House of Delegates in September last, S. 1620, as a whole and in many of its details, is unsound, and its enactment would not be in the public interest. Its enactment, it is believed, would prove a costly mistake, jeopardizing the welfare of the people and seriously compromising the future development of the science and art of medicine in the United States. If the federal and state taxes that will have to be imposed to carry this bill into effect must be imposed, then at least a substantial part of the proceeds had better be devoted to providing for the needy adequate food, clothing and shelter. So far as this bill is concerned, hunger, nakedness, cold and storm are to be left to wreak their damage, the bill proposing only to provide medical, hospital and nursing service to cure the damage for a while after it has been done.

If the principles laid down by the House of Delegates are unsound, the Association will welcome enlightenment. Fortunately, the proponents of this legislation have the opportunity of presenting their evidence in support of it before the House of Delegates of the Association meets in St. Louis, May 15-19. That will make it possible for the House to have such evidence before it in the course of its deliberations. If the House that is about to convene finds that modifications of the conclusions of the House that met in September last are called for, it will make such modifications.

Coming now directly to a discussion of the pending bill, I call attention to the fact that it proposes to authorize the imposition on the people of annual federal appropriations of variable amounts, ranging from $98,250,000 upward to an indefinite skyward limit and to require the states that cooperate with the federal government under the act to impose on their people proportionate state appropriations. It may seem paradoxical to speak of "imposing" appropriations on the people, but since every appropriation has implicit in it the taxes that have been or must be levied to provide the money appropriated, every appropriation that is made is "imposed" on the people just as truly as are the taxes themselves. The fact that an appropriation is primarily for the benefit of one class of the population while the taxes necessary to cover the appropriation fall directly on another class, possibly even on future generations, does not alter the situation.

So far as I am informed, no evidence has ever been offered to show that any of the projects embodied in S. 1620 were devised by any of the people of the several states or that the enactment of this legislation is being promoted by them. On the contrary, it is understood that every project embodied in this bill was devised by appointive federal officials and employees, to be handed down to the people on a "take it or leave it" basis. If the bill is enacted, the federal government will levy on the people the taxes necessary to provide for the payment of the cost of all activities authorized under the act and will then say to the people "Unless you come in on this venture, we keep every cent we have taken from you." Propaganda has been and is being organized to advance the plans of the federal proponents of this legislation, but the federal origin and driving force back of all these projects must not be lost sight of. The origin of these projects need not damn them, but it certainly lays on their federal organizers and proponents an even heavier burden of justification than they would have if the projects had originated in the several states. In meeting that burden, inasmuch as the taxes that the bill requires will fall on the people of all the states, its proponents are called on to justify it for each and every state; not for Alabama or Mississippi or Nevada alone but for New York, Pennsylvania, Massachusetts, Illinois and every other state. The prime necessity for such a state by state justification of this bill lies in the fact that, if there are states whose people are destitute and in distress beyond the power of their respective states to aid them, the Congress may appropriate for their relief on such terms as it sees fit, but without using such destitution and suffering in one state as an excuse or justification for imposing tax burdens and federal guidance and control on states whose people are not destitute or suffering and that are able to manage their own affairs.

It has been claimed in support of universality for legislation of this type that the federal taxation and the federal guidance and control that go with it are necessary:

1. To stimulate the states,
2. To equalize the health opportunities in all the states, and
3. To procure uniformity in health activities throughout the United States.

To lay the heavy hand of federal guidance and control on a state may serve quite as well to destroy its initiative as to stimulate it, and to subject every state to federal control and thus to establish uniformity may deprive the federal government of stimuli from the states; and stimuli from the states and a critical attitude on their part are as necessary to federal efficiency as are federal stimuli and criticism needed to insure state efficiency.

The phrase "to equalize the health opportunities in all the states" is a seductive phrase, but what assurance have we that the increase in taxation and the establishment of federal supervision and control to bring health opportunities to a common level, while raising the opportunities in some states, will not degrade the opportunities that exist in others and thus procure equality, certainly, but an equality of doubtful advantage?

To bring about uniformity of health activities among all the states would certainly tend to delay and possibly to diminish and to destroy opportunities in health endeavors for variation and experimentation that is possible under state control alone, which, under our normal constitutional form of government, furnish advantages that are too little appreciated and taken advantage of. The House of Delegates of the American Medical Association, at its special session in September last, emphasized particularly the need for the promotion of local initiative, supported by state aid and guidance if necessary, and by federal aid, guidance and control only when rendered necessary by the destitution or incapacity of the state.

The fact that the authority granted certain federal officers and the money placed at their command, by the Social Security Act, have not already reduced illness and disability to the extent apparently anticipated by some of the proponents of that act seems to have led to the demand in this bill for enlarged authority and more money, as if authority and money were together all sufficient to work miracles in the field of health. If this bill is enacted, in all probability within a year or two we shall have a repetition of our present experience, a demand for more authority and more money, in the vain hope of hastening a millenium in the field of health. But there is no royal road to health, either of the people as a whole or of individuals. Time and effort are required over long periods of years, and, even after such long periods, time and effort will be found to have produced smaller returns in some communities than in others; for conditions over which we have but limited control, such as race, heredity and meteorological conditions, may be the chief determining factors in causing diseases and death.

If the federal government can, in the brief ten years that has elapsed since the Sheppard-Towner Maternity and Infancy

Act was expressly repealed by the Congress, June 30, 1929 [Public No. 566, 69th Congress; 44 Stat. L. p. 1024], go as far as is proposed in this bill in spreading itself over intrastate activities in the field of health and medical service, there would seem to be no limit on its right to expand. A federal subsidy for police service might well give the federal government supervision and control of all police service throughout the country. A federal subsidy for the operation of state systems of assessment and tax collection might be devised to give the federal government supervision over state activities now regarded strictly as state functions. Possibly a line might be drawn against federal encroachment on the legislative activities of a state, but one can readily envisage a federal subsidy for the aid of state legislatures that would lead to the federal direction and control of their functions.

Concerning the action of the House of Delegates of the American Medical Association in special session in September last, there has been some misunderstanding and some misrepresentation. To make clear what the House did, it is necessary to go at some length into its proceedings. In doing so it is necessary to emphasize again the fact that the action of the House of Delegates at that time had reference not to S. 1620 but to the recommendations of the Technical Committee on Medical Care, an agency of the Interdepartmental Committee to Coordinate Health and Welfare Activities created by the President on which that bill seems to rest. It is therefore only as S. 1620 undertakes to translate into organization and action the recommendations of the Technical Committee that the action of the House of Delegates in September 1938 is pertinent.

1. The House of Delegates in September 1938 recommended the establishment of a federal department of health with a secretary at its head, who should be a doctor of medicine and a member of the President's cabinet. S. 1620 provides for no such officer. In fact, it proposes to leave the preventive and curative medical services of the federal government scattered as widely as ever through the federal organization.

2. The House of Delegates proposed that expenditures for the expansion of public health and maternal and child health services should not include the treatment of disease except so far as it could not be successfully accomplished through the private practitioner. The pending legislation purposes to provide for the treatment of disease under various conditions, without in any way safeguarding the existence of the private practitioner.

3. The House of Delegates favored the expansion of general hospital facilities where need exists and emphasized its approval of the recommendation of the Technical Committee stressing the importance of the use of existing hospital facilities. The House of Delegates did not endorse the committee's recommendation for an increase in special hospitals and for what the Technical Committee calls "health and diagnostic centers." S. 1620 includes no provision for the increased use of existing hospital facilities. It does not limit the expansion of general hospital facilities to situations in which need exists. It does propose an extensive program in the field of special hospitals and health, diagnostic and treatment centers.

4. The House of Delegates advocated recognition of the principle that the complete medical care of the indigent is a responsibility of the community and of the medical and allied professions and that such care should be organized by local units and supported by tax funds. It recognized the necessity for state aid for medical care in poorer communities. It proposed the limitation of federal aid to cases in which the state was unable to provide assistance for local communities. S. 1620 proposes to make federal aid for medical care the rule rather than the exception. Nothing has been found in it to limit to persons in need the medical care provided by federal funds.

5. The House of Delegates urged the importance of well coordinated programs for the improvement of food, housing and other environmental conditions for the prevention of disease and the promotion of health. It urged the establishment of a definite and far reaching public health program for the education and information of all the people, to enable them to take advantage of the medical service now available. For these basic needs for the prevention of disease and the promotion of health, S. 1620 makes no provision.

6. The House of Delegates refused to foster any system of compulsory health insurance. S. 1620 proposes to pave the way for compulsory health insurance by leaving to the Social Security Board the determination of what constitutes "methods of administration" necessary for the efficient operation of state plans for medical service. The provisions of the bill for grants to states for temporary disability compensation squint in the same direction. The House of Delegates approved the provision of compensation for loss of wages during sickness, but S. 1620 proposes to provide not merely for loss of wages but to provide medical services also.

7. The provisions of S. 1620, authorizing the chief of the Children's Bureau and the Surgeon General of the Public Health Service to set up what are termed "demonstrations," the provisions for the training of personnel, the provisions for an indefinite number of ill defined "advisory councils" and the provisions for the promulgation by various agencies, federal and state, of rules and regulations are matters that have never come before the House of Delegates of the American Medical Association. Obviously, they are all of serious import and will require careful consideration.

The House of Delegates authorized the appointment of ten physicians, under the chairmanship of Dr. Irvin Abell, President of the American Medical Association, to confer and consult with the proper federal representatives relative to the proposed National Health Program. This committee was not consulted in the framing of the pending bill. Had it been consulted, it is possible that through joint studies and investigations and mutual endeavor a bill would have been produced containing an irreducible minimum of issues between the medical profession of the country on the one hand, so far as it is represented by the American Medical Association, and, on the other hand, the proponents of this legislation, a consummation for which your committee might well most devoutly wish.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—The President on April 25 submitted to Congress Plan No. 1 on government reorganization. He proposed, among other things, to set up a new agency to be known as the Federal Security Agency, in which will be grouped the Social Security Board, the United States Employment Service, the Office of Education, the Public Health Service, the National Youth Administration and the Civilian Conservation Corps. At the head of this new agency is to be appointed an administrator with a salary of $12,000 a year. Representative Taber of New York introduced a concurrent resolution in the House, H. Con. Res. 19, proposing that the Congress reject the President's plan. This resolution was defeated by the House of Representatives May 3, and the President's Plan will become effective on the expiration of sixty calendar days after the date of its submission. S. 685 has passed the Senate, proposing to establish in the United States Public Health Service a Division of Water Pollution Control. S. 1416 has passed the Senate, proposing to make the provisions of the United States Employees' Compensation Act applicable to civil officers of the United States. S. 1964 has been reported to the Senate, proposing to authorize national banking associations to make charitable contributions. H. R. 2987 has passed the House, proposing to compensate any employee of the United States government who shall furnish blood for transfusion to a member or former member of the military establishment who is a patient in a government hospital.

Bills Introduced.—H. R. 5763, introduced by Representative Barry, New York, proposes to authorize national banking associations to make charitable contributions. H. R. 6068, introduced by Representative Knutson, Minnesota, proposes that on all ethyl alcohol withdrawn and used for other than beverage purposes the tax shall be $1.10 per gallon. S. J. Res. 107, introduced by Senator Sheppard, Texas, proposes to authorize the President to award the Congressional Medal of Honor to Dr. Anita Newcomb McGee "in recognition of her splendid service to the United States in organizing a corps of trained nurses for the United States Army during the period of the Spanish-American War and the Philippine Insurrection." S. 2107, introduced by Senator Reynolds, North Carolina, proposes to authorize a pension of $50 a month to all persons who served seventy days or more in the military or naval service of the United States during the Spanish-American War who have reached the age of 65 years, including any woman who

served honorably as a nurse, chief nurse or superintendent of the Nurse Corps under contract. Contract surgeons of the Spanish-American War may not qualify for this pension if the bill is passed. S. 2134, introduced by Senator Schwellenbach, Washington, and H. R. 5727, introduced by Representative Coffee, Washington, propose to amend the Longshoremen's and Harbor Workers' Compensation Act to extend the benefits of it to boommen and raftmen employed in lumbering operations on navigable waters. S. 2138, introduced by Senator Capper, Kansas, proposes to establish in the United States Department of Agriculture a Division of Cooperatives to conduct research in cooperative problems and furnish advisory service to cooperatives. S. 2284, introduced by Senator Walsh, Massachusetts, proposes to authorize the President to appoint in the Navy 100 acting assistant surgeons for temporary service.

STATE MEDICAL LEGISLATION

California

Bill Introduced.—A. 2809 proposes that "All persons, having the ability to pay therefor, and the individuals authorized by the laws of this state to treat the physical and mental condition from which such persons are suffering, and for which hospital facilities are required, are entitled, without discrimination, to the full accommodations, advantages, facilities, services and privileges of any hospital" in the state.

Bills Amended in the Assembly.—A. 2764 was so amended April 28 as to make it the duty of any physician or other person attending a birth to treat both eyes of the infant within two hours after birth with a prophylactically efficient treatment. A. 2177, to amend the workmen's compensation act, was so amended April 25 as to permit chiropractors and osteopaths to render the "medical treatment" which must be furnished injured workmen.

Florida

Bills Introduced.—H. 392 proposes to repeal the present naturopathic practice act and to enact a new practice act for such practitioners. The bill proposes to define naturopathy as "that system or school of medicine which is taught and practiced in the standard schools and colleges of Naturopathy." Such licentiates apparently will have the right to use x-rays, electro-therapy, anesthesia, antiseptics, germicides, parasiticides, narcotics and antidotes. The bill states that "Physicians of the Naturopathic School of Medicine are to be of equal rank and grade as the physicians of the other schools of medicine designated as allopathic, homeopathic and eclectic, to have all rights, except to practice major surgery and to use materials not taught in the standard colleges or schools of Naturopathy." S. 263 proposes to make it the duty of any person attending a confinement case, within two hours after the birth of the child, to instil in each eye of the child a prophylactic solution prescribed by the State Board of Health for the prevention of ophthalmia neonatorum. S. 306 and H. 352 propose to establish at Avon Park, in Highlands County, a branch of the Florida State Hospital for the care of insane persons. H. 527 proposes, as a condition precedent to the issuance of a license to marry, that each party to the proposed marriage present a certificate from a licensed physician stating that the party has been given such examination, including a standard serologic test, as may be necessary for the discovery of syphilis, made not more than thirty days prior to the application, and that, in the opinion of the physician, the party is either not infected with syphilis or, if so infected, is not in a stage of that disease which is or may become communicable to the marital partner.

Illinois

Bills Introduced.—H. 876 proposes to enact a separate drugless therapy practice act and to establish a board of examiners to examine and license applicants for licenses to practice drugless therapy. The bill proposes to define drugless therapy as "a biological, physiological, chemical and material health science and as such employs physical, laboratory or other methods of diagnosis or analysis and such other procedures necessary to proper diagnosis and treat human ailments, diseases, defects, injuries, functions or dysfunctions, abilities or disabilities of the human body by or with manipulations or correction of any displaced tissue of any kind or nature and by or with the administration of, employment or performance of, diet, food, biological substances, vitamins, minerals, herbs or other substances normal to or necessary to the functions of the human body and including mechanotherapy, electrotherapy, obstetrics, phytotherapy, irradiation therapy, psychotherapy, hydrotherapy, thermotherapy, physiotherapy, and physical therapy." H. 922, to amend the motor traffic code, proposes that, on the trial of a defendant charged with driving while under the influence of intoxicating liquor, the court may admit evidence as to the amount of alcohol in the defendant's blood at the time of the alleged commission of the offense, as shown by a chemical analysis of his urine, saliva, breath or other body substance. Evidence that there was, at the time of the alleged commission of the offense, 5 hundredths of 1 per cent, or less, by weight of alcohol in the blood is prima facie evidence that the defendant was not under the influence of intoxicating liquor sufficiently to impair appreciably his driving ability. Evidence that there was at that time from 5 hundredths of 1 per cent to 15 hundredths of 1 per cent by weight of alcohol in the blood is to be relevant evidence but is not to be given prima facie effect in indicating that the defendant was under the influence of intoxicating liquor. Evidence that there was at that time 15 hundredths of 1 per cent or more by weight of alcohol in the blood is prima facie evidence that the defendant was under the influence of intoxicating liquor sufficiently to impair appreciably his driving ability. H. 978 proposes to grant to a hospital caring for a person injured through the negligence of another a lien on all rights of action, claims, judgments and compromises accruing to the injured person because of his injuries. The total amount of the hospital's lien, however, is not to exceed one third of the sum paid or due the injured person.

Massachusetts

Bill Introduced.—H. 2206 proposes to create a special committee to investigate the advisability of the commonwealth's furnishing oxygen tents to stated hospitals.

Michigan

Bills Introduced.—S. 419 proposes to enact a new workmen's compensation act and to provide compensation for workmen suffering disability because of injuries or diseases arising out of and in the course of employment. The employer must pay for such medical, surgical or other attendance or treatment, nurse and hospital service, medicine, crutches and apparatus for such period as the nature of injury or the process of recovery may require. An employee is to be permitted to select his own physician from a list compiled by the department of labor on the recommendation of the medical societies of the several counties. A. 785 proposes to enact a law to regulate the manufacture, distribution and advertising of foods, drugs, cosmetics and devices.

Missouri

Bill Introduced.—H. 717 proposes to condition the issuance of a license to marry on the presentation by both parties to the prospective marriage of certificates signed by the parties in the presence of and executed by a licensed physician or by the director of a laboratory approved by the Department of Health that the parties are free from all venereal diseases.

New York

Bill Introduced.—S. 2021 proposes to continue until March 15, 1940, the temporary state commission created by chapter 743, Laws, 1937, to examine, report on and recommend measures to improve facilities for care of hard of hearing and deaf children and children liable to become deaf.

Pennsylvania

Bills Introduced.—S. 545 proposes to prohibit the operation of a private nursing home or a private hospital without a license from the Department of Welfare. The present law requires licensure for private nursing homes or private hospitals operated for profit. H. 688 proposes to require all hospitals receiving appropriations from the commonwealth to pay each intern an annual salary of not less than $1,000.

H. 1409 proposes a procedure whereby hospitals may be reimbursed by the state for care and treatment rendered indigents injured in motor vehicle accidents. S. 677 proposes to authorize the board of commissioners of any county of the third class to enter into agreements with general hospitals within its boundaries for the care of indigents and part-pay patients afflicted with contagious diseases. S. 732 proposes to require every hospital receiving an appropriation from the state to conclude contracts with all nonprofit hospital service associations authorized to operate within its area. H. 1401 proposes to enact an occupational disease act to provide compensation to workers contracting occupational diseases, as defined in the act, in the course of their employment. The bill proposes to define "occupational disease" to mean only poisoning by arsenic, lead, mercury, manganese, phosphorus, methanol, carbon bisulfide, hydrocarbon distillates or halogenated hydrocarbons, benzol or nitro amido or amino derivatives of benzol; caisson disease; radium poisoning or disability due to radioactive properties of substances or to roentgen ray; poisoning by or ulceration from chromic acid or bichromate of ammonium, potassium or sodium; epitheliomatous cancer or ulceration due to tar, pitch, bitumen, mineral oil or paraffin; infection or inflammation of the skin due to oils, cutting compounds, lubricants, dust, liquids, fumes, gases or vapor; anthrax; silicosis or anthraco-silicosis; and asbestosis.

OFFICIAL NOTES

THE ST. LOUIS SESSION

Special Radio Programs

The following radio programs have been arranged in connection with the annual session of the American Medical Association in St. Louis:

Dr. Irvin Abell, President of the Association, will broadcast over the Blue network of the National Broadcasting Company Monday, May 15, from 4:15 to 4:30 p. m. central standard time. His subject will be "American Medicine Today." Dr. Rock Sleyster, President-Elect, will broadcast over the Columbia Broadcasting System Monday, May 15, from 3:45 to 4 p. m. Dr. Sleyster will be interviewed by Miss Jane Stafford of Science Service.

Dr. W. W. Bauer, Director of the Bureau of Health Education of the American Medical Association, will broadcast over the Blue network of the National Broadcasting Company Friday, May 19, from 4:15 to 4:30. He will present a summary of the scientific and sociological developments at the meeting.

RADIO BROADCASTS

The radio broadcasts by the American Medical Association and the National Broadcasting Company, under the title Your Health, continue as previously announced each Wednesday over the Blue network of the National Broadcasting Company at 1 p. m. eastern standard time (12 noon central standard time, 11 o'clock mountain time, 10 a. m. Pacific time).

Starting April 30, daylight saving time took effect in Chicago. The program is therefore being broadcast at the same hour Chicago daylight saving time, which means one hour earlier central standard time, two hours earlier mountain time and three hours earlier Pacific time. In communities where daylight saving time is in effect there is no change in the hour of the broadcast.

Owing to network conflicts the Chicago broadcast does not occur at 1 o'clock Wednesday but there is a rebroadcast from a recording over station WENR at 8 o'clock each Monday evening (8 o'clock Chicago daylight saving time, 7 o'clock central standard time). The program broadcast each Monday is identical with the network program of the preceding Wednesday.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

May 17. Healthier Babies.
May 24. No broadcast because of radio conflicts occasioned by visit of British sovereigns to the United States.
May 31. Checking Up on Health.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Dr. Vinsonhaler Resigns as Dean.—Dr. Frank Vinsonhaler, dean of the University of Arkansas School of Medicine, Little Rock, has announced his resignation, effective July 1. He will become dean emeritus.

Personal.—Dr. Oneal L. Atkinson has been appointed health officer of Hampton.——Dr. Ralph M. Sloan has been elected a director of the Jonesboro Chamber of Commerce.——Dr. Roy J. Turner has been appointed health officer of Fayetteville. ——Dr. Albert S. J. Clarke, formerly of Clarendon, has been transferred as health officer in charge of district number 16 at Ozark.

District Meetings.—The Fourth Councilor District Medical Society was addressed in Pine Bluff recently by Drs. William M. Adams and John Cash King, both of Memphis, Tenn., on "Acute Trauma of the Face" and "Cooperation Between the General Practitioner and the Roentgenologist." ——At a meeting of the Sixth Councilor District Medical Society in Hope April 6, the speakers included Drs. Thomas E. Strain, Shreveport, La., on "Hypoglycemia in Children"; Joseph E. Knighton Sr., Shreveport, "Chronic Duodenal Pathology"; Sidney J. Wolfermann, Fort Smith, "Socialized Medicine," and Thomas P. Foltz, Fort Smith, "Acute Traumatic Craniocerebral Injuries."——The Third Councilor District Medical Society was addressed at Forrest City April 13 by Drs. John C. Ayres, Memphis, Tenn., on "Anesthesia and Obstetrics"; Rudolph B. McCormick, Memphis, "Infectious Diarrheas in Children"; Sidney J. Wolfermann, "Duodenal Ulcer from the Medical and Surgical Standpoint," and William R. Brooksher, Fort Smith, "Compulsory Sickness Insurance."

CALIFORNIA

School Named in Honor of Dr. Widney.—The Crippled Children's High School, on the grounds of Polytechnic High School, Los Angeles, has been named the "Dr. Joseph Pomeroy Widney High School." The building was completed last year at a cost of $100,000. The late Dr. Widney was the founder of the old college of medicine of the University of Southern California and once served as dean and later president of the university.

COLORADO

Society News.—Dr. Jesse G. M. Bullowa, New York, discussed pneumonia before the Medical Society of the City and County of Denver April 4. Dr. Rudolf Schindler, Chicago, will discuss gastroscopy before the society June 6 and give a clinical demonstration.——At a meeting of the Northeast Colorado Medical Society in Sterling March 9, Dr. William R. Lipscomb, Denver, discussed "Hypertension and Its Surgical Treatment."——The Pueblo County Medical Society was addressed in Pueblo March 7 by Dr. Theodore E. Wade on "Industrial Minor Injuries." Dr. Guy H. Hopkins addressed the society recently on "Ocular Palsies." At the former meeting Dr. Frederic J. Peirce was elected to honorary membership.

CONNECTICUT

The Harvey Cushing Festschrift.—The March number of the *Acta cl* [illegible] is dedicated as a festschrift to Dr. Har[illegible] professor of neurology emeritus, Yale [illegible] Medicine, New Haven, and Moseley professor of surgery emeritus, Harvard Medical School, Boston. The issue contains twenty-five papers, all but two of which are in English.

Society News.—A symposium on cancer and its relation to public health was presented before the New Haven County Public Health Association March 2 by Dr. Matthew Griswold, chief of the cancer research division of the state department of health; Miss Elizabeth Fox, director, New Haven Visiting Nurse Association; Dr. Ashley W. Oughterson, director, tumor clinic, New Haven Hospital, and Dr. John Mendillo, director, tumor clinic, Grace Hospital.——*Dr. Charles H. Best, Toronto,* discussed "Heparin and Thrombosis" before the Yale Medical Society, New Haven, March 8.

State Medical Meeting in New Haven.—The one hundred and forty-seventh annual meeting of the Connecticut State Medical Society will be held at the Hotel Taft, New Haven, May 25-26, under the presidency of Dr. Hugh B. Campbell, Norwich. The speakers will include:

Dr. Roy D. McClure, Detroit, Modern Treatment of Burns—Reduction in Death Rate (movie).
Dr. Addison H. Bissell, Stamford, Treatment of Wounds.
Dr. Edward J. Ottenheimer, Willimantic, Factor of Delay in Recognition of Common Surgical Conditions.
Dr. James Leonard Vickers, Greenwich, Essentials in Fracture Treatment.
Dr. Claude C. Kelly, Hartford, Problem of Cleft Lip and Cleft Palate.
Dr. Chris H. Neuswanger, Waterbury, Urogenital Deformities.
Dr. Arthur S. Griswold, Bridgeport, Congenital Orthopedic Deformities.
Dr. William J. German, New Haven, Management of Congenital Defects of Nervous System.
Dr. Herbert Thoms, New Haven, Essentials of Pelvimetry (movie).
Dr. Carl H. Wies, New London, Rational Therapy.
Dr. Sidney S. Chipman, Norwalk, Vaccines of Value.
Dr. Berkley M. Parmelee, Bridgeport, X-Ray Fallacies.
Dr. Robert Glen Urquhart, Norwich, The Apical Cavity in Pulmonary Tuberculosis.
Dr. Francis G. Blake, New Haven, Sulfapyridine in the Treatment of Pneumonia.
Dr. James R. Miller, Hartford, Treatment Procedures for Cancer of the Uterus Advised by the Connecticut Tumor Clinics.
Dr. Carl E. Johnson, New Haven, Dysmenorrhea.

Among others who will discuss the papers will be Drs. Arthur W. Allen, Boston; Thomas H. Lanman, Boston; Chester S. Keefer, Boston, and John R. Fraser, Montreal.

DELAWARE

Dr. Morris to Direct Birth Control Federation.—Dr. Woodbridge E. Morris, Dover, director, division of maternal and child health and of the crippled children's division of the state board of health, has resigned to become director of the Birth Control Federation of America, with headquarters in New York. Dr. Morris graduated at Johns Hopkins University School of Medicine, Baltimore, in 1933. The federation was formed by the recent merger between the American Birth Control League and the Birth Control Clinical Research Bureau.

DISTRICT OF COLUMBIA

Cancer Campaign.—A cancer-control program was launched April 1. Speakers for lay audiences were provided by the speaker's bureau of the Medical Society of the District of Columbia. The campaign was to be concluded at the end of the month although the educational program is to be permanent.

Hospital News.—A department of syphilology will be established at Garfield Hospital to provide facilities for diagnosis, clinic treatment and hospitalization. To be known as department L, the new division will be in charge of Dr. William H. Hough, and Dr. Russell J. Fields will be director in charge of clinical work. There will also be a social service worker. Services and drugs will be free to those unable to pay.

Society News.—At a meeting of the Washington Ophthalmological Society March 6 Drs. Walter O. Teichmann and Edgar Leonard Goodman spoke on "Skin Lesions Around the Eye" and "Muscle Tendon Transplantation for Paralysis of External Rectus."——The George Martin Kober Medical Society was addressed recently by Dr. Frank M. Hand on "A General Reference to the Extremities of the Body" and Otto H. Wendt, D.D.S., "Eruption of Three Sets of Superior Central Incisor Teeth: Case Report."——Dr. William F. Rienhoff Jr., Baltimore, discussed "Peptic Ulcer" before a meeting of the naval medical and dental officers March 6.——A panel discussion on "Recent Advances in the Anemias" was presented before the Washington Society of Pathologists May 10; Dr. Elbert DeCoursey was the mediator and Dr. Roger M. Choisser the leader.

GEORGIA

Society News.—The Ware County Medical Society was addressed in Waycross April 5 by Dr. Thomas J. Ferrell, Waycross, on "Ruptured Peptic Ulcer."——At a meeting of the Colquitt County Medical Society in Moultrie March 17 Dr. James A. Redfearn, Albany, spoke on "The Nervous Patient."——A meeting of the Georgia Medical Society in Savannah March 28 was addressed by Dr. Richard F. Slaughter, Augusta, on "Cranial Cerebral Trauma." Dr. Samuel F. Rosen, Savannah, reported a case of Bazin's disease.——At a meeting of the Fulton County Medical Society April 20, among others, Drs. William Howard and Hugh E. Hailey discussed "Pruritus Ani et Vulvae and Its Relation to Other Allergic Conditions." Among others, Dr. John F. Denton, Atlanta, presented a paper before the society April 6 entitled "Radium and X-Ray in the Treatment of Gynecologic Conditions."

IDAHO

Changes in Health Officers.—Dr. George H. Bischoff, health officer of Bannock County, has been appointed director of the maternal and child welfare and crippled children's division of the state department of health. He will be succeeded by Dr. James V. Foley.

Society News.—A recent meeting of the North Idaho Medical Society was addressed in Lewiston by Drs. Jean D. Kindschi and Robert H. Southcombe, both of Spokane, Wash., on "Syphilis in Pregnancy" and "Newer Treatments in Psychiatry" respectively.——A special meeting of the Pocatello Medical Society was recently addressed by Drs. Cleveland J. White on skin diseases; James K. Stack, injuries of the wrist, and Stanley Gibson, treatment of respiratory diseases in children. The same speakers who are members of the staff of Northwestern University Medical School, Chicago, addressed the South Side Medical Society recently and the Southwestern Idaho District Medical Society.

ILLINOIS

Physician Honored.—Dr. William F. Scott, Maywood, for many years chief of staff of the Oak Park Hospital, was guest of honor at a dinner April 26 given by the Sisters of Misericorde in honor of his many years of service as chief of the staff of the hospital. Members of the staff presented to the hospital an oil portrait of Dr. Scott, which is to be hung in the hospital gallery, and Dr. Scott was presented with a memorial volume containing the signatures of his friends and associates. Dr. Austin A. Hayden, Chicago, was toastmaster.

Chicago

Dr. Szent-Gyorgyi Will Speak on Oxidation.—Dr. Albert Szent-Gyorgyi, professor of medical chemistry, Royal Hungarian Franz Josef University, Szeged, Hungary, will lecture in the Palmer House May 26 under the auspices of the Institute of Medicine of Chicago, on "The Mechanism of Biological Oxidation."

The Annual Hedblom Lecture.—*Dr. John Alexander*, professor of surgery, University of Michigan School of Medicine, Ann Arbor, will deliver the annual Hedblom lecture sponsored by the Phi Beta Pi Fraternity of the University of Illinois College of Medicine May 17. His subject will be "The Management of Bronchiectasis and Abscess of the Lung."

Personal.—Dr. Max Cutler, director of the Chicago Tumor Institute, recently returned from a cruise around South America in which he gave nine addresses before medical associations and universities. The Chicago Tumor Institute has granted one fellowship to each of the South American countries for graduate instruction in the field of cancer. The fellows will be selected by the deans of the medical schools and the ministers of health.

INDIANA

Society News.—Dr. James O. Ritchey discussed "Serum Treatment of Pneumonia" before the Indianapolis Medical Society April 25 and Drs. Kenneth G. Kohlstaedt and Irvine H. Page, "Sulfapyridine Treatment of Pneumonia." Dr. Andrew C. Ivy, Chicago, discussed "Practical Application of the Newer Concepts of the Physiology of the Digestive System" before the society recently. A symposium on gynecologic surgery was presented before the society March 28 by Drs. Carl Habich, Dudley A. Pfaff, John William Hofmann and Ross C. Ottinger.

IOWA

Instructors in First Aid.—Forty-nine persons received first aid proficiency certificates at the graduation exercises of a Red Cross first aid training course recently completed in Fremont County. Twelve physicians of the county medical society, under the direction of the president, Dr. Ralph Lovelady, Sidney, served as instructors for the group of sixty-two adults, who met each week from Oct. 31, 1938, to Feb. 6, 1939. Personal instruction in bandaging and splinting procedures was given and a demonstration of various resuscitation appliances was conducted. In addition, five minute talks on symptoms, home treatment and prevention of some of the communicable diseases were presented.

KENTUCKY

Home of Ephraim McDowell Restored.—The home of Dr. Ephraim McDowell at Danville has been restored as a memorial to him and to his patient, Mrs. Jane Todd Crawford, and will be formally dedicated May 20. The dedicatory address will be delivered by Dr. Irvin Abell, chairman of the memorial

committee, and President, American Medical Association, and Gov. A. B. Chandler will give the speech of acceptance. A dinner will be held in the evening. The restoration work was done by the WPA and the Commonwealth of Kentucky. The home was presented to the state by the Kentucky State Medical Association.

MAINE

Society News.—Dr. Thomas A. Foster, Portland, discussed "Pyuria in Infants and Children" before the Androscoggin County Medical Association, Auburn, March 16.——Dr. Richard H. Overholt, Brookline, discussed "Developments in the Management of Chest Lesions" before the Cumberland County Medical Society April 21 in Portland.——Dr. Samuel A. Levine, Boston, addressed the Kennebec County Medical Association, Gardiner, April 20, on "Auscultation of the Heart."——At a meeting of the Knox County Medical Association in Rockland, April 11, Dr. Siegfried J. Thannhauser, Boston, spoke on vitamin deficiencies.

MASSACHUSETTS

Health Week in Lynn.—A special program sponsored by the Lynn Young Men's Christian Association marked the twelfth annual "Greater Lynn Health Week" March 11-19. "Youth Health" was the theme of this year's observance. Lectures, radio broadcasts and exhibits were features of the program.

Society News.—Dr. Harry Goldblatt, Cleveland, discussed "Experimental Observations on the Pathogenesis and Treatment of Hypertension" before the New England Heart Association April 28.——Among others, Drs. Frank H. Lahey and Everett D. Kiefer, Boston, addressed the New England Roentgen Ray Society April 21 on "Carcinoma of the Thyroid" and "Lesions of the Small Bowel."——The speakers before the New England Pathological Society in Wrentham April 20 included Drs. Clemens E. Benda, Wrentham, on "The Bone Development in Mongoloid Deficiency"; Thomas G. Cogswell, Worcester, "Epidermoid Cysts"; Harry M. Zimmerman, New Haven, Conn., "Nervous System Lesions in Hyperinsulinism," and Milton C. Winternitz, New Haven, on "Arteriosclerosis."

MICHIGAN

The Hickey Lecture.—Dr. Byrl R. Kirklin, Rochester, Minn., delivered the third annual Hickey Memorial Lecture before the Wayne County Medical Society, Detroit, April 3 on "Bleeding Lesions of the Gastro-Intestinal Tract and Their Roentgenologic Diagnosis."

Portrait of Dr. McKean.—An oil painting by Roy Gamble of the late Dr. George E. McKean will, when completed, be placed permanently in the headquarters of the Wayne County Medical Society. It will be unveiled at the annual meeting of the county medical society. Dr. McKean was president of the society 1919-1920 and served on the board of trustees from 1921 to 1933.

Examination of Mexican Beet Field Workers.—A cooperative plan for protecting the health of Michigan communities from contagious diseases among imported Mexican beet field workers was announced March 10 by the state department of health. The four state associations of sugar beet growers have agreed to pay half the expense of health examinations of field workers before they are brought from Texas and to employ no worker who has not passed a physical examination showing that he is free from tuberculosis and syphilis in infectious stages. The state health department will provide the other half of the cost of the examinations with the aid of funds allotted from the U. S. Public Health Service. The examinations will be made in Texas before the workers are hired by the sugar beet growers' associations. About 10,000 Mexican beet field workers are imported into the state during each growing season and diseases found among these laborers in the past have been a danger to the health of several Michigan communities. According to the state department, an outbreak of Shiga dysentery in Shiawassee County last summer was attributed to this source.

MISSISSIPPI

Personal.—The Gulf Coast Medical Society recently gave a dinner in honor of Dr. Daniel J. Williams, Gulfport, who has been health officer of Harrison County for twenty-five years; he is also a past president of the state medical association.——Dr. William W. Reynolds, Meridian, was recently appointed superintendent of the Matty Hersee Hospital, a state-supported institution, succeeding Dr. George Lamar Arrington.

Society News.—The Delta Medical Society was addressed in Greenville April 12 by Drs. Ira B. Bright, Greenwood, on "Electrocardiogram as an Aid to Diagnosing Heart Conditions"; Joseph G. Peeler, Shaw, "Sulfanilamide—Its Use in General Practice"; Onnie P. Myers, Indianola, "The Management of Diabetes in Country Practice"; Earl T. White, Greenville, "Cancer of the Colon"; James R. Jackson, Belzoni, "Allergy," and Orren W. Hyman, Ph.D., Memphis, Tenn., "What the Present Trend Toward Socialized Medicine Is Going to Do to the General Practitioner."

MONTANA

A Pneumonia School.—According to the *Journal-Lancet* a pneumonia school available to physicians and laboratory technicians in western Montana was recently held at Montana State University, Missoula, under the auspices of the university and the state board of health. The speakers were Drs. Ernest D. Hitchcock, Great Falls; Meredith B. Hesdorffer, Missoula; Raymond F. Peterson, Butte; Burton K. Kilbourne, Helena, and Miss Edith Kuhns, Helena, director of the hygienic laboratory for the state board of health.

NEW JERSEY

New Committee to Control Cancer.—A New Jersey State Committee for the Control of Cancer has been organized to coordinate activities of lay and professional groups, under the auspices of the county medical societies and the American Society for the Control of Cancer. The committee aims to assist medical societies in securing facilities for the treatment of cancer as well as to carry on a campaign of educational publicity. Dr. Joseph H. Kler, New Brunswick, chairman for New Jersey of the American Society for the Control of Cancer, is also chairman of the new committee which is composed of representatives of both medical and non-medical groups.

NEW YORK

Smallpox Reported.—Smallpox has occurred in the village of Colonie, Albany County. The first case was in a man, never vaccinated, who conducts a gas station and trailer camp at stop 19 on the Albany-Schenectady Road. A systematic follow-up of all persons known to have been exposed to the gas station proprietor and his wife was carried out. Widespread publicity was given to the occurrence of these cases.

Personal.—Dr. George Emory Lochner, Albany, was guest of honor at a dinner March 15 given by the board of trustees of the Anthony N. Brady Maternity Home to celebrate his completion of fifty years in the practice of medicine. Dr. Lochner has been chief of staff of the Brady home since its establishment.——The Dutchess County Medical Society gave a dinner April 12 in Poughkeepsie in honor of Dr. Robert W. Andrews, who is moving to Texas after practicing in Poughkeepsie more than forty years. Dr. John C. McClintock, Albany, addressed the meeting of the society on thyroid problems.

New York City

Committee to Study Forensic Psychiatry.—The mayor has appointed a group of physicians and lawyers to serve as a committee to originate a plan of forensic psychiatry to pass on the mentality of persons under charges in New York courts, it is reported. The appointment was made when provision for pay for lunacy commissions was dropped in the city budget. The New York Academy of Medicine, the Bar Association of the City of New York and the New York County Lawyers Association will cooperate in the study which will be in charge of William B. Herlands, commissioner of investigation. Included on the committee will be Drs. John A. Hartwell and Israel Strauss, Mr. George Sylvester and Mr. Irving Brawer.

Another Physicians' Orchestra.—Announcement is made of the formation of the Doctors Orchestral Society of New York. Officers are Drs. Leopold Glushak, president; William S. Thomas, vice president; Charles Auer, treasurer, and Harold Belcher, secretary. Ignatz Waghalter is the conductor. The society plans to hold its premiere in the Town Hall May 26 with Ernest Schelling, American pianist-composer, as soloist. The proceeds of the affair will be donated to the Physicians' Home and the Loan and Relief Fund of the Medical Society of New York. The program will include:

Overture to "Oberon"	Weber
Symphony No. 5 in E minor "From the New World"	Dvořák
Concerto for Piano and Orchestra in A minor	Schumann
"Emperor" Waltz	Strauss

Personal.—Dr. Chrisman G. Scherf, medical superintendent of Metropolitan Hospital, has been named to a similar position at the new Hospital for Chronic Diseases on Welfare Island, according to a recent announcement by the commissioner of hospitals, Dr. Sigismund S. Goldwater. The new hospital will open about July 1, it was stated.——Dr. Victor G. Heiser received the gold medal of the Holland Society of New York April 6 in recognition of his "distinguished service to public health."——Dr. Alexis Carrel of the Rockefeller Institute for Medical Research was awarded the gold service medal of the Rotary Club of New York April 13 "in recognition of a life devoted to the amelioration of human suffering."——Dr. Shirley W. Wynne, former health commissioner, has been named commissioner of the Manhattan Council, Boy Scouts of America.——Dr. Thomas M. Rivers, director of the Hospital of the Rockefeller Institute for Medical Research, has been appointed to the New York City Board of Health by Mayor La Guardia to succeed the late Dr. Carl Boettiger.

NORTH CAROLINA

District Meetings.—Dr. Beverley R. Tucker, Richmond, Va., was the guest speaker at a meeting of the Second District Medical Society in Greenville April 13, on advancements in the treatment of the mentally ill.——The Fifth District Medical Society held a meeting in Lumberton April 6 with the following speakers, among others: Drs. David Henry Poer, Atlanta, on surgical management of goiter; James M. Ruffin, Durham, diagnosis and treatment of conditions causing bloody diarrhea, and Russell S. Beam, Lumberton, sulfapyridine in pneumococcic infections.——The Tenth District Medical Society met in Asheville March 31 in conjunction with the state board of health and the extension bureau of the University of North Carolina. Dr. Robert E. Seibels, Columbia, S. C., spoke on the care of pregnant women. Dr. Horton R. Casparis, Nashville, Tenn., spoke on care of children in infancy.

OHIO

Personal.—The John and Mary Markle Foundation, New York, has awarded a grant of $4,100 to Dr. Carl J. Wiggers, professor of physiology, Western Reserve University School of Medicine, Cleveland, to study the nature of ventricular fibrillation.——Dr. Harry Goldblatt, Cleveland, recently received the "grand scientific award" of the Phi Lambda Kappa fraternity in recognition of his work on essential hypertension.

The Rachford Lectures.—Dr. Ernest W. Goodpasture, professor of pathology, Vanderbilt University School of Medicine, Nashville, Tenn., delivered the Benjamin Knox Rachford Lectures at the University of Cincinnati April 13-14. His subjects were "Experimental Virus Infections of the Chick Embryo" and "Experimental Bacterial Infections of the Chick Embryo." The Rachford Lectureship was established in 1929 in memory of Dr. Rachford, who organized the department of pediatrics in the university.

PENNSYLVANIA

Narcotic Addicts and Epileptics Barred from Driving.—More than 28,000 known narcotic addicts have been barred from obtaining licenses and driving permits in Pennsylvania. They will not be allowed to drive until they can show on competent medical authority that they are cured. The report also said that 5,000 applicants known to be subject to epilepsy have been refused permits and 259 are waiting for special hearings.

Philadelphia

Sectional Meeting on Physical Therapy.—The spring session of the American Congress of Physical Therapy, under the auspices of the New York Physical Therapy Society and the Pennsylvania Physical Therapy Association, was held at Jefferson Medical College, Philadelphia, April 22. Among the speakers were:

Dr. John H. Willard, Abdominal Neuralgia.
Dr. Karl Harpuder, New York, Physical Therapy in Peripheral Vascular Disease.
Dr. Louis Kaplan, Physical Therapy in Fractures Treated with Unpadded Cast.
Dr. Kristian G. Hansson, New York, After-Treatment of Infantile Paralysis.
Dr. Abraham R. Hollender, Chicago, Controversial Problems in Nasal Iontophoresis.
Dr. Gustave Bucky, New York, New Developments in Grenz Rays.
Dr. Jean Saidman, director, Institute of Actinology, Paris, New Methods of Physical Diagnosis and Physical Therapy.
Dr. Joseph T. Beardwood Jr., Philadelphia, Newer Methods of Physical Therapy in the Treatment of Complications of Diabetes.

Pittsburgh

Second Renziehausen Lecture.—Frank G. Young, Ph.D., a member of the scientific research staff of the National Institute for Medical Research, London, England, delivered the second Renziehausen Memorial Lecture at the Mellon Institute April 24. His subject was "The Anterior Pituitary Gland Diabetes." These lectures were established recently by Miss Emilie Renziehausen in memory of her brothers.

SOUTH CAROLINA

Hospital News.—A new Oconee County hospital at Seneca was opened February 6 with accommodations for forty patients. Construction of the hospital was a WPA project representing an outlay of about $75,000.

Society News.—Dr. Frederic W. Schlutz, Chicago, addressed the Columbia Medical Society in Columbia April 10 on "Sulfanilamide Therapy in Pediatric Practice" and Dr. LeGrand Guerry, Columbia, "Reconstruction of Bile Passages Based on a Study of Fifteen Consecutive Cases."

VIRGINIA

Personal.—William T. Sanger, LL.D., president of the Medical College of Virginia, Richmond, received the honorary degree of doctor of humane letters, from Bridgewater College April 3, when he made a Founder's Day address. Dr. Sanger will receive the degree of doctor of laws from the University of Richmond at its June commencement.——Dr. James Brooke Pettis, recently on the staff of the New Jersey State Hospital, Marlboro, N. J., has been appointed director of clinical psychiatry.

Society News.—Dr. Tiffany J. Williams, Charlottesville, addressed the Danville-Pittsylvania Academy of Medicine, April 11, on "Toxemias of Pregnancy."——Dr. Hugh C. Henry, Richmond, has been elected president of the Neuropsychiatric Society of Virginia; Dr. Thomas N. Spessard, Norfolk, vice president, and Dr. Edward H. Williams, Richmond, secretary.——Dr. Edwin C. Hamblen, Durham, N. C., was the guest speaker at the spring meeting of the Southwestern Virginia Medical Society in Bristol April 13 on endocrinology.

WASHINGTON

Hospital News.—A new Shriners' Hospital was dedicated recently in Spokane adjacent to St. Luke's Hospital, where the original building was erected in 1924. Erected at a cost of $85,000, the new building will provide facilities for the care of crippled children.

Spokane Surgical Meeting.—Dr. Edward William Alton Ochsner, New Orleans, was the guest speaker at the annual meeting of the Spokane Surgical Society April 8. Dr. Ochsner gave the following addresses: "Peripheral Vascular Disease," "Thrombophlebitis" and "Surgical Significance of Amebiasis." Members of the society presented papers and conducted clinics.

Graduate Course.—The University of Washington announces its annual extension graduate medical course July 17-21. Instructors this year will include Drs. Andrew C. Ivy, Howard C. Ballenger, Newell C. Gilbert, George H. Gardner and Charles Marshall Davison, all of the staff of Northwestern University Medical School, Chicago. Clinics will be conducted at King County Hospital by local physicians.

WEST VIRGINIA

Personal.—Dr. Walter E. Vest, Huntington, will receive the honorary degree of doctor of science at the June commencement of the Medical College of Virginia, Richmond. Dr. Vest graduated from the college in 1909.

Society News.—Dr. Samuel Iglauer, Cincinnati, addressed the Ohio County Medical Society, Wheeling, April 21, on "Deep Infections of the Neck and Mediastinum."——Dr. Thomas E. Jones, Cleveland, addressed the Ohio County Medical Society April 7 on "Abdominoperineal Resection" and Dr. Leon Herman, Philadelphia, March 24, on "Urinary Infections in the Pregnant Woman."——Dr. Hugo Roesler, Philadelphia, addressed the Kanawha Medical Society, Charleston, April 11 on "Nonmechanical Diagnosis of Heart Lesions."

WISCONSIN

Society News.—Dr. John W. Harris, Madison, addressed the Milwaukee Society of Clinical Surgery March 28 on "An Evaluation of the Various Operative Procedures for the Correction of Uterine Prolapse" and Dr. Edmund H. Mensing,

Milwaukee, on "Prophylaxis of Peritonitis."——The Medical Society of Milwaukee County and the Milwaukee County Dental Society held a joint meeting March 10; the speakers were Dr. Elmer L. Sevringhaus, Madison, on "The General Features of Mineral Metabolism" and Isaac Schour, Ph.D., D.D.S., Chicago, "Calcification of the Tooth as an Index of the Constitutional Pattern of the Child."

GENERAL

American Board Examinations in Ophthalmology.—The American Board of Ophthalmology will conduct a written examination in various cities of the United States, in Honolulu, Puerto Rico and Canada August 5. Formal application for this examination must be received before July 1. General oral examination for successful candidates will be held in Chicago October 7. For information, write at once to the secretary, Dr. John Green, 6830 Waterman Avenue, St. Louis.

Awards for Chemical Research.—Among awards for research in chemistry for the academic year 1939-1940 by the Lalor Foundation, Wilmington, Del., are the following of medical significance: Otto Karl Behrens, Ph.D., Rockefeller Institute for Medical Research, New York, for work on chemistry of peptide metabolism; Andrew Calvin Bratton, Ph.D., instructor in pharmacology and experimental therapeutics, Johns Hopkins University School of Medicine, Baltimore, chemical aspects of chemotherapy of compounds of the sulfanilamide type.

Health Conference in Rio de Janeiro.—The eighth biennial conference of the Health Section of the World Federation of Education Associations will be held in connection with the congress of the federation in Rio de Janeiro, Brazil, August 6-11. A working conference is being developed in which all present will share experiences in health education, health services and physical education in the schools. Brief outlines of each paper will be read when the author, or a representative of his country, is present and before the close of each of the four sessions a summary of the papers and discussions will be presented and acted on by the group. Program and travel information can be obtained from the executive secretary, Health Section Secretariat, 200 Fifth Avenue, New York.

Association for the Study of Goiter.—The American Association for the Study of Goiter will hold its annual meeting in Cincinnati May 22-24. The tentative program includes the following speakers:

Dr. Willard O. Thompson, Chicago, Management of Severe Thyrotoxicosis.
Dr. Elmer C. Bartels, Boston, Coronary Disease in Myxedema.
Dr. Douglas U. McGregor, Hamilton, Ont., Tuberculosis of the Thyroid Gland.
Drs. Samuel F. Haines, Thomas B. Magath and Fred H. Powers, Rochester, Minn., The Hippuric Acid Test in Hyperthyroidism.
Drs. Brien T. King and Frederick Lemere, Seattle, A New and Function-Restoring Operation for Bilateral Abductor Cord Paralysis.
Dr. Warren H. Cole, Chicago, Anesthesia in Thyroidectomy with Special Reference to Avertin.
Drs. Elliott C. Cutler and Stanley O. Hoerr, Boston, Avertin Anesthesia for Thyrotoxicosis.

Awards in National Traffic Safety Contest.—New Jersey won the grand prize for states and Providence, R. I., the grand prize for cities in the annual national traffic safety contest sponsored by the National Safety Council. All states and 1,163 cities participated in the contest. Three other states won first place in their geographic divisions: Oklahoma, Iowa and Washington. Six cities won awards in their population groups: Cleveland and Milwaukee tied among cities with populations of 500,000 or more; Trenton, N. J., 100,000 to 250,000; Saginaw, Mich., 50,000 to 100,000; Waukegan, Ill., 25,000 to 50,000, and Mason City, Iowa, 10,000 to 25,000. Providence won first place in the 250,000-500,000 population group. In addition to these awards the judges gave prizes and honorable mention and named a special honor roll of 157 cities with populations between 5,000 and 10,000 which went through 1938 without a traffic death. New Jersey cut its traffic deaths in 1938 to 885 from 1,378 in 1937. Providence had sixteen traffic deaths in 1938 as compared with forty-one in 1937. The average death rate for all prize winning cities in the contest was 9.9 per hundred million miles traveled; the national average for cities was 14.5. Scoring of the contest was based on a maximum score of 100 possible points. The motor vehicle death rate counted for 50 points and the remaining fifty points were divided among accident reporting systems, traffic engineering and enforcement, child safety programs and public education. Bronze plaques were presented to the governors of the states and mayors of the cities were presented at a dinner at the Mayflower Hotel, Washington, D. C., April 13.

Sulfapyridine in the Treatment of Pneumonia

The use of sulfapyridine for pneumonia is the leading therapeutic topic of the day. At the Royal Society of Medicine Dr. L. E. H. Whitby said that the efficacy of this drug had been fully confirmed. Provided the patient could live for twenty-four hours and retain some 5 Gm. the chance of success was greatly increased, whatever the day of the disease on which the treatment was begun. The scheme of dosage of Gaisford and Evans, from 4 to 5 Gm. the first twenty-four hours and 3 Gm. daily thereafter to a total of 25 Gm., was the usual one followed. Stopping administration of the drug within four days was followed by an exacerbation, which in animals was difficult to control. Whether passive immunization with serum or active immunization with vaccine should be combined with the use of sulfapyridine was difficult to say. Patients treated on the fifth day and afterward required only 15 Gm. to produce a crisis and cure. The basic indication for the drug was a definite coccic infection. It had no action on influenza. Its chief disadvantage was gastric irritation and vomiting in about 30 per cent of cases.

Dr. W. F. Gaisford reported a year's hospital experience with sulfapyridine in which he had treated between 600 and 700 patients suffering from infections of the respiratory tract. Of these 400 had lobar pneumonia. Children under the age of 5 years and patients dying within twelve hours of admission to the hospital were not included in the statistics. The total mortality dropped from 23 per cent before the use of the drug to between 6 and 7 per cent. In patients over 50 the drop was from 50 to 24 per cent; in patients under 50, from 17 to 1.6 per cent. In nearly all cases the effect on the temperature was shown by a fall to normal within forty-eight hours of the beginning of treatment. Continuance of pyrexia indicated either a complication or an organism that was not the pneumococcus. There was no indication of any alteration in the rate of resolution. The general condition rapidly improved after the fall in temperature. Toxic effects of the drug were slight, rashes similar to but less severe than those produced by sulfanilamide. Cyanosis was observed in some cases, but it ceased to be a worrying sign. Vomiting sometimes occurred but was rarely so persistent as to prevent retention of a sufficient dose of the drug.

Prof. Alexander Fleming said that sulfapyridine did not seem to kill the pneumococcus, which presumably was killed by the natural defenses of the body. The mortality might be still further reduced if patients were immunized when the drug was given. There was not much time to develop active immunity, but animal experiments indicated that not much active immunity was required when combined with drug treatment.

Dr. Maurice Davidson sounded a note of warning against the indiscriminate way the sulfanilamides were being used by the junior members of the profession. We were not yet in a position to say that they did not cause damage. A drug so potent as to be able to deal effectively with a virulent organism might possibly damage renal epithelium or even the myocardium. The president, Dr. H. L. Tidy, said that the responsibility for the wild use of these drugs in general practice lay with the travelers of drug firms.

Operation for Paralyzed Muscles

The physiologist Prof. W. A. Osborne of Melbourne, in conjunction with Basil Kilvington, showed in 1907 that the regenerating fibers of the cut sciatic nerve of the dog do not travel down the original paths but even cross from one division

to another. The Australian surgeon N. D. Royle has ingeniously turned this pathologic fact to account in the treatment of paralysis (*M. J. Australia* **1**:227 [Feb. 11] 1939). He points out that in anterior poliomyelitis degeneration of a peripheral nerve may follow degeneration of the spinal neuron and that the nerve trunk may contain both normal fibers and sheaths with degenerated fibers. If the nerve is interrupted and allowed to regrow, some healthy fibers will grow into sheaths containing degenerated fibers and so reach the paralyzed muscles, which will regenerate, for Royle has obtained return of power in four successive cases. In one the tibialis anticus was paralyzed and in another all the muscles supplied by the median and ulnar nerves. In the latter case nerve suture and transplantation were performed, in addition to nerve section below the line of transplantation. Royle now adds another typical application.

A boy aged 4 had paralysis from injury of the brachial plexus at birth. There was loss of power in the hypothenar eminence and in the interosseus muscles of the left hand, but the muscles of the forearm supplied by the ulnar nerve had recovered. Royle exposed the ulnar nerve above the elbow and crushed it with strong artery forceps in several diameters so as to disorganize the axis cylinders. A year later the boy had regained power in the paralyzed muscles. The muscles considered by Royle suitable for this operation are the tibialis anticus, which in poliomyelitis often remains paralyzed when other muscles of the anterior tibial group recover, the intrinsic muscles of the thumb, the interossei, the peronei, individual muscles of the posterior peroneal group and any paralyzed muscle in an otherwise normal group. The crushing of the nerve must be done at some distance proximal to its first muscle supply. Thus in the common peroneal nerve it must be done at least 5 cm. above the origin of the supply of the muscles and in the ulnar nerve 1 inch or more above the elbow. The usual orthopedic practice is followed while recovery of the paralyzed muscles is being awaited.

Prevalence of Brucellosis in France

A report was presented at the February 21 meeting of the Académie de médecine of Paris by Drs. Dubois and Sollier on the incidence and prevention of brucellosis in France. More than 4,000 cases were reported last year, with a mortality of from 6 to 7 per cent. The disease is almost exclusively of animal origin. Of 100 cases, the infection originates in about eighty in sheep, in fifteen in goats and in only about five in cows. There is danger, however, of pigs acting as sources of infection. With the exception of certain portions of Brittany the disease has been reported from every department in France. The object of the report was to draw attention to the inefficacy of present sanitary laws against the disease and the necessity of vaccination of every person in an infected area. Experience has shown that only about one case in twenty or twenty-five is reported. Fortunately this does not have any serious results, because disinfection of the surroundings of the patients with brucellosis has been shown to be of little value. Interhuman contagion is exceptional. The chief value of a declaration of the disease is that it enables the authorities to discover new foci of animal brucellosis and thus enables human beings in that locality to be aware of the dangers surrounding them. Unfortunately, owing to the small number of cases reported by farmers, most of the centers of infection in sheep and goats remain undiscovered. The majority of the sanitary measures are inadequate because of certain circumstances, which include the fact that the mode of contagion is complex in animals; there are certain species which are specially susceptible and there is a possibility for the female to be apparently well and yet be a carrier to an unlimited degree.

VACCINATION

As to prophylaxis, efforts to vaccinate animals against the disease have given only negative results. In general only killed bacteria have been used, but Dr. Dubois has employed since 1934 living and virulent cultures of Brucella abortus suis. Sheep vaccinated by this method have resisted experimental brucellosis as well as a natural form of the disease. At the same time they have not been infectious for animals of the same species in spite of a contact of from one to two years. A study of 480 cases of undulant fever since 1930 shows that seven of eight persons were infected after direct or indirect contact with infected animals and only one of eight after ingestion of milk or cheese. It is impossible to avoid infection of persons whose daily work brings them into constant contact with infected animals. The only method of prophylaxis for human beings is the use of a polyvalent vaccine containing strains of Brucella melitensis of human, sheep and goat origin and also strains of Brucella abortus bovis and suis. The use of such vaccine was begun by the authors in 1929, and more than 5,000 persons have been vaccinated, of whom 3,800 were farmers and 1,200 persons engaged in slaughterhouses or veterinary work. The unquestionable value of this method of vaccination is shown by the fact that undulant fever was observed in numerous nonvaccinated persons, whereas those who had been equally exposed but previously vaccinated were immune.

The New Wiener Medizinische Gesellschaft

In the train of events under the new régime in Austria the famous Gesellschaft der Aerzte, like many other time-honored organizations, has lately been dissolved. In 1937 the centenary of the society was celebrated in a manner befitting so illustrious a medical body. The greatest German names in the world of medicine enthusiastically participated in this celebration. The list of speakers and scientific lecturers was brilliant and in keeping with the accomplishments of the society and its reputation. But its continuance was not to be tolerated by the Nazi rulers of Vienna, and, like all other medical societies, it was disestablished, in the 101st year of its existence. In its stead a new Wiener medizinische Gesellschaft was created, designed to serve medical practitioners and scientific research. Naturally only Aryan doctors are admitted to membership and in addition foreigners who are unquestionably in sympathy with the régime. The plan of the new society includes sections for the various special disciplines to take the place of the former societies of specialists. There is also newly added a special section for military medicine. The president of the new society is no distinguished clinician; he is the Nazi district governor of Vienna, that is to say a politician who is also an official of the Nazi bureau of national health.

In his inaugural address, February 4, the new president himself stated that he was well aware that many representatives of science were not wholly in accord with the establishment of the new organization under political rather than under scientific auspices. The president is Dr. O. Planner-Plan. This political control has become necessary, he stated, because as district governor he is better informed about local public health affairs than any one else. Since he has the representatives of science at his beck and call, it is possible for him to draw on consultant opinion in any problem which may arise. As he put it, "Prominent representatives of the various specialties may be commissioned to give an opinion with regard to any questions, and thus their abundant knowledge will be made to serve the nation's health." Dr. Planner-Plan's address was embroidered with a wealth of detail, which may be briefly summarized: The present speedy tempo of the national work program in Germany

not only should be maintained but should be surpassed. This means that a maximal expenditure of energy will be demanded of all German workers and soldiers. A further objective is conservation of the prolonged efficiency of the nation's workers. In this connection the physicians have an important mission to fulfil. Specializing physicians, too, have their respective duties, which the president went on to enumerate.

At each session of the new society a lecture and demonstrations will be given. It is further planned to correct certain bad features of medical practice; above all, an endeavor will be made to effect better collaboration between directors of clinics and specialists active as consultants.

THE NAZI CREED WITH REGARD TO MEDICINE

The principal address at the inaugural session was delivered by Prof. Franz Hamburger, ordinarius in pediatrics (and successor of Pirquet), long known for his Nazi sympathies. He climaxed his talk with the following pronouncement: "National socialism means a revolution in every sphere of our civilization and culture. No phase of western culture is unaffected by it. Most noteworthy of all, and what must remain most noteworthy, is the revolution in the realm of medical science, in the field of public health." The speaker went on to say that, despite the achievements of natural science within the past 150 years, medicine had been on the wrong track. "Medicine has now progressed beyond its old frontiers and has broken out of its shell, thanks to the philosophy and deeds of the führer." The healing art of yesterday has become the planned hygiene of today, the medical knowledge of mankind. Thus pediatrics becomes the medical study of children, gynecology the medical study of women, and so on. "With admirable clarity and logic the führer points the way into these fields, "like a physician by the grace of God he shows us the path to health." The rubbish of which physicians must free themselves is the dross of misapplied science, that pseudoscience in medicine which opposes itself to the clearly ascertainable facts of everyday experience. Hamburger then assailed "that freedom from preconception" which has been such a source of pride. "A real renascence of medical science, on Nazi foundations, must take place." That which is taught by university professors must be completely founded on the tenets of the Nazi program of life and health. "This should be easier for him (the teacher) because national socialism rests on an absolutely sound biologic basis." The chief spokesmen of the various medical disciplines at the universities must be confirmed Nazis; this applies especially to clinicians. Hamburger went on to deprecate the "arrogance of physicians" and to put in a good word for "nature medicine," which, he said, ought not to be too lightly esteemed. "National socialism, unlike any other political philosophy or party program, is in accord with the natural history and biology of man. And because national socialism considers all known physiologic data from nature and from human behavior, it merely represents truths about man. It is accordingly well suited to the direction of the health of our people." Hamburger then turned his fire in succession on Catholicism, liberalism and socialism. He next entered into a discussion of several general problems, in the course of which he said that only a wrongly educated, intellectually biased patient would wish to know the diagnosis—and more along the same line.

Gain in Weight Among Soldiers

The status of body weight is a good measuring rod for the evaluation of the health of youthful persons. Interest therefore attaches to a recent report published by a ranking health officer, Colonel-Surgeon Dr. H. Müller of the sanitary corps of the army. All recruits are weighed during the first half year of their service monthy and later quarterly. The weight is recorded each time in the health statistics of the troops. To obtain an idea of the trends in body weight among young soldiers of the entire reich, statistics on the routine weighings have been compiled by the army health inspector (namely the highest officer in the medical corps in peace time). In the summer of 1938 separate reports were compiled on the recruits who had entered service in November 1937 and soldiers who had already served one year. For both groups the body weight at the time of enlistment was compared with the body weight in the summer of 1938. This represented the first time that such a complete record had been made. The observations were as follows: After the first half year of military training, 70 per cent of the recruits had gained weight, the weight of 10 per cent remained the same and 20 per cent had lost weight. The corresponding figures for men at the end of one year's service were: gained weight 73 per cent, weight stationary 9 per cent and lost weight 18 per cent. It was thus ascertained that in general the tendency to gain weight ends after the first half year. For the entire army the mean increase in weight during the first year amounted to around 3 Kg.

AUSTRALIA

(From Our Regular Correspondent)

March 29, 1939.

Another Plan Replaces National Health Insurance

Following the commonwealth government's decision to abandon its scheme for national health insurance as embodied in the National Insurance Act of 1938, it is intended to substitute a medical service plan. In view of the increased and increasing liabilities incurred on account of defense measures (£500,000 a week in Australia) and the prospective additional cost of liberalizing the national insurance plan as laid down in the act, together with a decreased ability on the part of the government and the people of Australia to meet the cost of maintenance of the scheme, the government has decided to repeal entirely the pension provisions of the act. There remains a system of health insurance and family medical benefit. Details of the scheme have not been determined, but the weekly contribution of 1 shilling sixpence each from employer and employee as provided in the present act is to be reduced approximately by half. It is intended to continue the approved society system and the cash health benefits on substantially the same scale as is now provided. But the whole question of medical benefit is to be discussed first with representatives of medical benefit organizations and of the medical profession and later with the consultative council of approved societies. The announcement that the health service is not to be abandoned makes the matter acute once more for general practitioners in Australia. Now, however, they are well organized to present a united front against governmental aggression and to press their arguments for control of medical services by a board composed mainly of medical men, for the reduction of the income limit for insurance patients, and for the acceptance of certificates and prescriptions from any registered practitioner. It is obvious from a survey of the legislative background in Australia that any hope of finality in the arrangements for "national" insurance is remote.

New Development in Maternity Service

To reduce further maternal mortality figures, the health department of New South Wales has made available better medical facilities for mothers during the puerperal period. Antepartum and postpartum facilities have been set up and are expanding. The scheme now propounded will cover the vital intermediate period. Arrangements include an agreement with the state branch of the British Medical Association whereby the services of accredited obstetric consultants will be made available in any abnormal maternity case, no matter what the financial circumstances of the patient may be, and the establishment of a mobile blood transfusion unit which

will be attached to one of the metropolitan hospitals. Blood donors will be paid at the rate of £5 for every pint of blood taken from them, and the whole of this cost, together with that of bringing in specialists, will be borne by the department of public health. Furthermore, any maternal death occurring will be reviewed within a reasonable time by a special committee, with a view to discovering any loopholes in the scheme and thus to reduce the rate of any similar happening in the future.

Extension of Pharmaceutic Training Suggested

With the advent of New Zealand's social security act of 1938, it becomes imperative that increased laboratory facilities for diagnosis and treatment be made readily available to medical practitioners throughout the country. Rather than bring into existence some new organization, it would be preferable if this were undertaken by an existing body having contact with both the physician and the patient, and for this reason it has been suggested that pharmacists suitably trained in the practice of biochemical analysis would be able to give this service to the state. Such an arrangement insures adequate laboratory services in a form easily available to physician and patient.

The first requisite in any such plan would be to insure an adequate standard among those pharmacists who undertook the work. A diploma of biochemical analysis would certify that the holder was qualified to carry out the work by virtue of his having passed examinations in the subject. Only those pharmacists who held such a diploma would be qualified to carry out this work, and the tests would be performed only on the order of a qualified medical practitioner. As the pharmacist already has the foundations of the required knowledge of general chemistry and of chemical analysis, it appears that he would be the logical person to train for the work.

The scope of the work would include (1) urinary tests and estimations (routine chemical examination, urea concentration test, quantitative analyses for sugar, albumin and chlorides, test of the diastatic activity and fermentative sugar test), (2) blood analyses (dextrose tolerance test, urea estimation and estimation of total nonprotein nitrogen), (3) serum analyses (test for calcium, cholesterol and phosphates, quantitative Van den Bergh test, qualitative Van den Bergh test and protein estimation), (4) fecal analyses (detection of occult blood and estimation of fats) and (5) fractional gastric analyses.

This suggestion has been greeted by various criticisms. While the scheme may look well on paper, practical laboratory experience suggests that there is an element of false security inherent in the proposal. The absence of immediate medical direction for this type of work and the lack of interpretative facilities may lead to error. The range of biochemical work also warrants a turnover, an equipment and a degree of application which are unlikely to be found in even a well equipped pharmacy. The tendency in Australia is to employ a technician of the caliber of a bachelor of science to do this type of work in conjunction with a technician or, sometimes, to combine the two positions when the turnover is limited. But in either case medical direction is given to the work. The suggestion also affects the future of the medical graduate who has specialized in pathology and biochemistry. While the "pathologic unit" working in a well equipped laboratory finds ample scope in towns of a population of about 100,000, a difficulty arises as to what type of unit is suitable for towns and districts of smaller population. Here a better solution of the problem would be the establishment of "pathologic units" at strategically selected centers: the problems of distance between the unit and the scattered practitioners being overcome by modern methods of communication and transport, including the airplane. The pharmaceutic chemist could still be used, but over a much more limited range of technical activities.

BELGIUM

Feb. 16, 1939.

Congress of Neurology and Psychiatry

The Congress of Neurology and Psychiatry, organized by neurologic and psychiatric societies of Belgium and the Netherlands, held its sessions at Ghent and at Brussels under the chairmanship of Prof. C. U. Ariëns Kappers. In the first paper the literature of dementia praecox and the encephalitides was reviewed. Dr. Guillaume Vermeylen said that numerous cases of psychoses and notably of dementia praecox have as their basis an encephalitis. These encephalitides often develop insidiously and their nature is as yet poorly defined. They may be the result of a direct influence of the virus or of a state of asthenia which permits a neurotropic virus to become virulent. Moreover, these divergent hypotheses assume a diminution of resistance in the hemato-encephalic barrier. The more highly developed the patient's psychosis, the more diffuse is the cerebral process; and the slower the development of the process, the greater the chances that organized psychoses will be observed to develop.

The second paper dealt with parenchymatous disorders of the cerebellum. Bernard Brouwer and Arie Biemond hold the opinion that the cerebellum is an organ of association for the proprioceptive system and consequently an organ of coordination, above all for the involuntary movements. The activity of the cerebellum renders the movements quicker and easier, since at the cerebellar level no associations of another order come to disturb its functioning, as happens at the level of the hemispheres. The latter may interfere at any time with the physiologic activity of the cerebellum and thus modify the mechanism of motility, but they cannot completely replace the cerebellum in this function.

Occupational Dermatoses

Dr. Henri Halkin has published in the *Liége médical* an article on occupational dermatoses. Certain dermatoses are truly based on the occupation proper, whereas the environment is of minor importance in their manifestation. The principal disorders are due to cement and lime in general, to chromium and the chromates, and to concentrated acids or alkalis, and to globules of oil. Nearly 80 per cent of cutaneous accidents are occupational dermatoses, cutaneous reactions in Brocq's sense of the term. However, in addition to an external cause, there usually is a general disturbed condition of the patient's equilibrium. This concept may be invalidated as soon as more information has been obtained with regard to the phenomena of sensitization.

Ernest Malvoz

Dr. Ernest Malvoz, the recently deceased professor of bacteriology at the University of Liége, was a pioneer in social medicine. For him the highest humanitarian duty was "to combat the three greatest scourges: ignorance, poverty and disease."

Marriages

MARION KEMPER HUMPHRIES JR., Charlottesville, Va., to Miss Zaida Pettit Thomas of Wytheville, April 15.

ARTHUR C. JOHNSON, Omaha, to Mrs. Lotus Hulsebus of Pasadena, Calif., at Las Vegas, Nev., February 17.

CLEMENT P. O'NEILL, Rock Island, Ill., to Miss Baptista Hummer of Davenport, Iowa, April 10.

RUSSELL LEE NORBURN to Mrs. Hope Robertson Colthup, both of Asheville, N. C., April 10.

CHARLES SCOTT MILLER to Miss Ethel Atkinson, both of Philadelphia, recently.

JACOB SALVATORE DIGATE to Miss Edith Alberts, both of Chicago, March 18.

HARRY SHUBIN to Miss Celia Fierman, both of Philadelphia, July 9, 1938.

Deaths

Arthur H. Harrington ⊕ Providence, R. I.; Jefferson Medical College of Philadelphia, 1882; an Affiliate Fellow of the American Medical Association, past president of the Rhode Island Medical Society; member of the American Psychiatric Association and the New England Society of Psychiatry; medical director of the Bridgewater (Mass.) State Hospital, 1894-1898, superintendent of the Danvers (Mass.) State Hospital, 1898-1903, New York Eye and Ear Infirmary, 1903-1907, and State Hospital for Mental Diseases, Howard, 1907-1926; aged 82; died, March 12, of arteriosclerosis and coronary occlusion.

John W. Burns ⊕ Cuero, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1891; member of the House of Delegates of the American Medical Association, 1922-1932, 1934-1938, and since 1937 member of the Judicial Council; past president of the State Medical Association of Texas and the De Witt County Medical Society; fellow of the American College of Surgeons; formerly member of the state board of health; medical director of a hospital bearing his name; aged 72; died, May 1.

Charles B. Barker, Guthrie, Okla.; Chicago College of Medicine and Surgery, 1912; member of the Oklahoma State Medical Association and the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; aged 54; died, February 12, in St. Anthony Hospital, Oklahoma City, of streptococcic septicemia.

Martin Donelson ⊕ Medical Inspector Commander, U. S. Navy, retired, Danville, Va.; University of Virginia Department of Medicine, Charlottesville, 1906; member of the American Urological Association; entered the navy in 1907 and retired in 1935 for incapacity incident to the service; aged 56; was found dead, February 9, of a bullet wound.

Jules Baechler, West New York, N. J.; Columbia University College of Physicians and Surgeons, New York, 1907; member of the Medical Society of New Jersey; for many years medical examiner for the public schools; aged 61; died, February 11, in the North Hudson Hospital, Weehawken, of cerebral hemorrhage and hypostatic pneumonia.

Lester Jarvis Benson, Lakewood, Ohio; Chicago Homeopathic Medical College, 1903; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; honorary member of the staff of the Lakewood City Hospital; aged 78; died, February 12, of acute pulmonary edema and osteoarthritis.

William Chestnut, Winnipeg, Man., Canada; Manitoba Medical College, Winnipeg, 1898; professor emeritus of medicine at his alma mater; for many years on the honorary attending staff and formerly medical superintendent of the Winnipeg General Hospital; aged 71; died, February 7, of coronary occlusion.

Cornelia Bernhardine Johanna Schorer ⊕ Foxboro, Mass.; Universität Zürich Medizinische Fakultät, Switzerland, 1897; an Affiliate Fellow of the American Medical Association; member of the American Psychiatric Association; formerly on the staff of the Foxboro State Hospital; died, January 9, in Berlin, Germany.

Reynolds May, Whitewright, Texas; University of Louisville (Ky.) Medical Department, 1878; member of the State Medical Association of Texas; past president of the Grayson County Medical Society; formerly member of the board of education; aged 87; died, January 2, in a hospital at Sherman of heart disease.

Reuben C. Burrow, Cunningham, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1891; Eclectic Medical Institute, Cincinnati, 1894; member of the Kentucky State Medical Association; past president and secretary of the Carlisle County Medical Society; aged 70; died, February 2, of pneumonia.

Walter Barwick Bruce, Helena, Ark.; University of the South Medical Department, Sewanee, Tenn., 1901; member of the Arkansas Medical Society; county health officer; for many years member of the board of trustees of the University of the South, Sewanee, Tenn.; aged 65; died, February 22, of cerebral hemorrhage.

Amos H. Caffee ⊕ Terre Haute, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1900; past president of the Vigo County Medical Society; secretary of the city board of health; served during the World War; on the staff of the Union Hospital; aged 73; died, February 1, of coronary thrombosis.

Frank Joseph Alessi, Niagara Falls, N. Y.; University of Buffalo School of Medicine, 1929; on the staffs of the Memorial Hospital and St. Mary's Hospital, Niagara Falls, and the Millard Fillmore Hospital, Buffalo; aged 34; died, January 10, in Saranac Lake of pulmonary tuberculosis.

Justin M. De Ford, Rossburg, Ohio; Cincinnati College of Medicine and Surgery, 1892; member of the Ohio State Medical Association; for many years member of the local board of education and at one time member of the county board of education; aged 82; died, March 4, of pneumonia.

William Heilman Hossler, Staten Island, N. Y.; Medical College of Ohio, Cincinnati, 1907; formerly acting assistant surgeon in the United States Public Health Service, Immigration Department; aged 59; died, January 13, in the United States Marine Hospital of diabetes mellitus.

Edward Homer Egbert, St. Simon Island, Ga.; Baltimore Medical College, 1905; member of the Medical Association of Georgia; served during the World War; formerly surgeon to the Huggins Hospital, Wolfeboro, N. H.; aged 57; died, February 27, of coronary thrombosis.

John H. Fletcher, Wichita Falls, Texas; St. Louis College of Physicians and Surgeons, 1905; veteran of the Spanish-American and World wars; city health officer and formerly county health officer; aged 60; died, January 29, in a local hospital of cirrhosis of the liver.

Robert Jasper Alexander ⊕ Waco, Texas; Memphis (Tenn.) Hospital Medical College, 1891; fellow of the American College of Surgeons; on the staffs of the Providence and Central Texas Baptist sanitariums; aged 72; died, February 20, of acute hypostatic pneumonia.

Philip James Reichmann, Oakwood, Mo.; St. Louis College of Physicians and Surgeons, 1911; member of the Missouri State Medical Association; aged 61; died, January 11, in St. Elizabeth's Hospital, Hannibal, of diabetes mellitus and gangrene of the left foot.

William Thomas Asher, Atlanta, Ga.; Atlanta Medical College, 1893; member of the Medical Association of Georgia; on the staffs of St. Joseph Infirmary and the Grady Hospital; aged 67; died, February 7, of cerebral thrombosis and cerebrovascular degeneration.

Alfred Mitchell Merriman ⊕ Bristol, R. I.; Medical School of Maine, Portland, 1895; at one time medical inspector of the public schools; formerly on the staff of the Rhode Island Soldiers' Home; aged 70; died, January 9, in the Jane Brown Hospital, Providence.

John Norris Doyle, Wausau, Wis.; Marquette University School of Medicine, Milwaukee, 1915; member of the State Medical Society of Wisconsin; served during the World War; aged 53; died, February 4, in a hospital at Temple, Texas, of pneumonia.

Charles Daligny, Troy, N. C.; Université de Paris Faculté de Médecine, France, 1878; member of the Medical Society of the State of North Carolina; served in the Franco-Prussian War; aged 85; died, January 8, of carcinoma of the prostate and uremia.

Howard Newell Baker, Pierson, Iowa; Hahnemann Medical College and Hospital, Chicago, 1905; member of the Iowa State Medical Society; formerly a member of the board of education; aged 57; died, February 8, of cerebral hemorrhage.

Charles Joseph King, Langdon, N. D.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; Dearborn Medical College, Chicago, 1906; aged 59; died, January 31, of coronary occlusion.

Chester Roy Brigham, Polo, Ill.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1905; member of the Illinois State Medical Society; served during the World War; aged 66; died, February 27, of coronary thrombosis.

Clarence Hathorne Staples, Malden, Mass.; Harvard University Medical School, Boston, 1904; member of the Massachusetts Medical Society; on the staff of the Malden Hospital; aged 60; died, January 17, of cerebral hemorrhage.

Marcus James Greenlee, Sewickley, Pa.; Howard University College of Medicine, Washington, D. C., 1937; aged 28; died, January 24, in the Suburban General Hospital, Bellevue, of skull fracture received in an automobile accident.

Lincoln Riegel Light, Lebanon, Pa.; Jefferson Medical College of Philadelphia, 1892; member of the Medical Society of the State of Pennsylvania; aged 71; died, January 12, of cerebral hemorrhage, arteriosclerosis and hypertension.

Archibald D. Campbell, Richland Center, Wis.; Louisville (Ky.) Medical College, 1896; aged 73; on the staff of the Richland Hospital, where he died, February 18, of bronchopneumonia, arteriosclerosis and chronic myocarditis.

John James Lindsay, Spartanburg, S. C.; University of Maryland School of Medicine, Baltimore, 1887; member of the South Carolina Medical Association; aged 73; died, January 5, at the Spartanburg General Hospital.

Edward Joseph Howland ⊕ Colchester, Conn.; University of Vermont College of Medicine, Burlington, 1911; served during the World War; for many years health officer; aged 58; died, January 25, of coronary thrombosis.

Lee H. Duguid, Michigan Center, Mich.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1898; served during the World War; aged 66; died, January 8, in the United States Marine Hospital, Detroit.

William Frederick Vilter, Cincinnati; Medical College of Ohio, Cincinnati, 1901; member of the Ohio State Medical Association; on the staff of the Deaconess Hospital; aged 62; died, January 21, of lymphatic leukemia.

Frank Edward Tompkins, Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1899; aged 62; died, January 1, in the Boro Park General Hospital of chronic nephritis and uremia.

Thomas Francis Shinnick, Beloit, Wis.; Rush Medical College, Chicago, 1899; member of the State Medical Society of Wisconsin; served during the World War; aged 65; died, January 29, of heart disease.

John Stephen Thompson, Winterport, Maine; Georgetown University School of Medicine, Washington, 1895; aged 75; died, January 8, in Antigonish, N. S., of anemia and acute dilatation of the heart.

Charles Lewis Hawkins ⊕ Taft, Calif.; Jefferson Medical College of Philadelphia, 1900; member of the American Urological Association; aged 68; died, January 14, of abscess about the ampulla of Vater.

Ada Scott Conner Morton, Fall Brook, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; aged 59; died, January 11, of angina pectoris.

William Lincoln Shawk, Rockaway Beach, Calif.; Western Reserve University Medical Department, Cleveland, 1883; aged 78; died, January 7, of arteriosclerosis and cerebral hemorrhage.

Winfield Howard Ames, Milford, N. H.; Syracuse University College of Medicine, 1893; aged 70; died, January 25, of abscess of the axilla following injury by crutch, and hemophilia.

Ross David Long, Oklahoma City; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1899; aged 69; died in January of cerebral arteriosclerosis.

Joe Johnson Taylor, Riverside, Calif.; American Medical College, St. Louis, 1893; St. Louis College of Physicians and Surgeons, 1908; aged 72; died, January 6, of chronic myocarditis.

Jefferson Davis Duke, Heflin, Ala.; Southern Medical College, Atlanta, Ga., 1884; member of the Medical Association of the State of Alabama; aged 77; died, February 12, of hemiplegia.

William Patrick Brogan, Tyler, Texas (licensed in Texas, under the Act of 1907); member of the State Medical Association of Texas; aged 67; died, January 6, of arthritis deformans.

Charles Leona Badger, Indianapolis; Indiana University School of Medicine, Indianapolis, 1911; aged 60; died, February 5, in St. Vincent's Hospital of an overdose of a narcotic.

Kenneth Paul Hunter, Wapello, Iowa; State University of Iowa College of Medicine, Iowa City, 1927; served during the World War; aged 39; died, January 15, of heart disease.

Frank Milton Hamblin, Bristol, Conn.; New York Homeopathic Medical College and Hospital, 1899; aged 65; died, January 30, in a hospital at Middletown of arteriosclerosis.

James Johnson Ellis, Knoxville, Tenn.; Tennessee Medical College, Knoxville, 1899; member of the Tennessee State Medical Association; formerly state senator; aged 80; died, January 5.

John A. P. Shields, Hartford, Tenn.; Chattanooga Medical College, 1902; member of the Tennessee State Medical Association; formerly state senator; aged 69; died, January 17.

David C. Trach ⊕ Kresgeville, Pa.; College of Physicians and Surgeons, Baltimore, 1891; aged 71; died, January 8, in the University of Pennsylvania Hospital, Philadelphia.

Nelson Du Val Brecht, Washington, D. C.; George Washington University School of Medicine, Washington, 1906; aged 54; died, February 15, of a self-inflicted bullet wound.

Joseph McClanahan Cornett, Temple, Texas; Baylor University College of Medicine, Dallas, 1934; intern at the Scott and White Hospital; aged 24; died in January.

Edward Sax Drucks, Oakland, Calif.; College of Physicians and Surgeons of San Francisco, 1907; member of the California Medical Association; aged 55; died, January 9.

James Krauss, Boston; Boston University School of Medicine, 1889; fellow of the American College of Surgeons; aged 72; died, January 29, of bronchopneumonia.

Joseph Price Dancy, Detroit; Howard University College of Medicine, Washington, D. C., 1920; aged 44; died, February 13, in the Parkside Hospital of meningitis.

Frank Joseph Doyle, Baltimore; Georgetown University School of Medicine, Washington, D. C., 1901; aged 60; died, February 5, of valvular heart disease.

Ellis Reynolds Shipp, Salt Lake City; Woman's Medical College of Pennsylvania, Philadelphia, 1878; aged 92; died, January 31, of carcinoma of the neck.

William S. Manners, San Leandro, Calif.; Northwestern Ohio Medical College, Toledo, Ohio, 1888; aged 82; died, January 28, of chronic myocarditis.

James H. West, McCrory, Ark. (licensed in Arkansas in 1905); aged 59; died, January 29, in the Baptist Hospital, Memphis, Tenn., of heart disease.

Calvin S. De Voll, Fort Worth, Texas; Metropolitan Medical College, Chicago, 1900; aged 86; died, February 19, of uremia and cardiorenal disease.

Osborne Elliott Carr, Owen Sound, Ont., Canada; University of Toronto Faculty of Medicine, 1913; aged 52; died, February 23, of heart disease.

Julian Philip M. Johnson, Yuba City, Calif.; State University of Iowa College of Medicine, Iowa City, 1910; aged 65; died, January 25, in India.

Jacob Koronefsky ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1900; aged 69; died, January 16.

John Clemons Lancaster, Houston, Texas (licensed in Texas under the Act of 1907); aged 87; died, January 31, of bronchopneumonia.

Alice Maud Gray, Boston; Tufts College Medical School, Boston, 1900; member of the Massachusetts Medical Society; died, January 17.

Vincent Millasich, Fresno, Calif.; California Medical College, San Francisco, 1906; aged 81; died, January 28, of cerebral hemorrhage.

Ulysses S. Ammerman, Reynolds, Neb.; Keokuk (Iowa) Medical College, 1898; aged 74; died, January 19, of coronary thrombosis.

William Noble Nanney, Whittier, Calif.; Medical College of Evansville, Ind., 1878; aged 85; died, January 12, of chronic myocarditis.

George Henry Baker, Long Branch, N. J.; Albany (N. Y.) Medical College, 1886; aged 84; died, February 8, of bronchopneumonia.

Stuart Eccles Beech, Salmon Arm, B. C., Canada; Manitoba Medical College, Winnipeg, 1911; aged 54; died, January 29.

William O. Curlee, Lubbock, Texas (licensed in Texas, under the Act of 1907); aged 62; died, February 7, of coronary disease.

Stephen Sinclair Slauenwhite, Windsor, N. S., Canada; Halifax (N. S.) Medical College, 1896; aged 72; died, January 12.

Arthur E. Fraleigh, St. Mary's, Ont., Canada; Western University Faculty of Medicine, London, 1892; died, January 17.

Morton Lake Hooper, Goldsboro, N. C.; Baltimore Medical College, 1887; aged 81; died, January 22, of chronic myocarditis.

John W. J. Newman, Buchanan, Ga.; Atlanta Medical College, 1893; aged 73; died in January of heart disease.

Charles H. A. Meyer, Baltimore; Baltimore Medical College, 1888; aged 78; died, January 1, of heart disease.

Marjory Ward, Renfrew, Ont., Canada; Trinity Medical College, Toronto, 1894; aged 68; died, January 25.

Robert G. Turner, Nacogdoches, Texas (licensed in Texas, under the Act of 1907); aged 62; died, January 2.

Gardner Spring Chapin, Los Angeles; Rush Medical College, Chicago, 1903; aged 59; died, January 1.

A PROGRAM FOR THE REFUGEE PHYSICIAN

To the Editor:—The purpose of this statement is to inform the medical profession at large of the facts concerning refugee physicians in this country and to offer a just and reasonable program to resolve the existing problem to the mutual advantage of the communities in which they are seeking shelter and of the émigrés themselves.

Until recently current misconceptions about the facts and a lack of understanding of the nature of the situation have added needless difficulties and complications. The committee hopes that this statement will serve primarily to clarify the facts in order to provide a better spirit of understanding in terms of mutual responsibility.

THE FACTS

During the period from July 1, 1934, to Dec. 1, 1938, corresponding to the time of the National Socialist régime in Germany, 1,528 physicians have migrated to the United States from Greater Germany.

The official figures covering this period are the following:

July 1, 1934, to July 1, 1935	104
July 1, 1935, to July 1, 1936	253
July 1, 1936, to July 1, 1937	286
July 1, 1937, to July 1, 1938	365
July 1, to Dec. 1, 1938	520
	1,528

Of this number, approximately 25 per cent are Catholic or Protestant and 75 per cent are of Jewish or partly Jewish origin.

There are at present 170,000 physicians in the United States, and our own medical schools graduate 5,500 new physicians each year. Despite this, the number of physicians in relation to the general population has been steadily decreasing, from 1 to 662 in 1886 to 1 to 784 in 1934.

THE PROBLEM IS SELF LIMITED

On the basis of the situation abroad, there will be a substantial reduction in the number of refugee physicians entering this country in future years, since:

1. Those who now apply for admission to this country must wait three or four years for their quota numbers to become available.

2. An indication of the limited nature of the problem is furnished by official Berlin statistics, published in the Sept. 17, 1938, issue of THE JOURNAL, revealing that there were fewer than 2,500 Jewish doctors left in Germany proper on July 1, 1938. Of these some have since emigrated to all parts of the globe. Approximately 700 have permits to practice among the Jews left in Germany. It is estimated that there are hardly more than 1,000 potential medical emigrants in Germany itself. In this connection, an item in the New York *Times* of April 26, 1939, dealing with Jewish emigration from Germany, is of particular interest: "Significantly enough, the only Jews whose emigration is being discouraged are physicians, especially surgeons, who might prove useful in case of war."

The quotas for admission to the United States from Poland, Hungary, Rumania and Czechoslovakia are so small that in any one year not more than an aggregate of 200 to 300 physicians could possibly enter from these countries.

3. Many of the Jewish physicians remaining in Germany are advanced in years. Many are close to the age of retirement.

4. Students of the type who later might have to emigrate can no longer enter the medical schools in Greater Germany, Czechoslovakia, and so on. In the eastern European countries, restriction of entry for such students in medical schools has been in practice for years, and we need anticipate no significant immigration of physicians into the United States from these countries.

The peak load has clearly been passed. The concentration of the refugees on the Eastern Seaboard has created an exaggerated impression of their actual numbers, either present or future. Therefore the committee feels that the question has now become one of the proper selection and distribution of a limited number of physicians and that an adequate and practical solution can be found based on a carefully studied and administered plan.

THE STRUCTURE

The Committee for the Resettlement of Foreign Physicians has been organized under the egis of the nonsectarian National Coordinating Committee for Aid to Refugees. Since New York City is the port of entry for the large majority of immigrants the central office is located at 165 West Forty-Sixth Street. However, there is a national committee composed of representatives of members of the local committees, such as the Boston Committee on Medical Emigrés (Dr. David Edsall, chairman), the Baltimore committee (Dr. John M. T. Finney, chairman) and the Chicago committee (Dr. Dallas B. Phemister, chairman), as well as of the New Haven and New Jersey committees which are being formed. The New York committee works in close cooperation with these committees, but since the initial task of selection devolves on New York, the following organization has been set up:

Members of the General Advisory Council include Dr. George Baehr, Dr. Clarence G. Bandler, Dr. Ernst P. Boas, Dr. Louis Casamajor, Dr. Alfred E. Cohn, Dr. Lewis A. Conner, Dr. Haven Emerson, Dr. N. Chandler Foot, Dr. Frank Fremont-Smith, Dr. Irving Graef, Dr. Foster Kennedy, Dr. John D. Kernan, Dr. Lawrence S. Kubie, Dr. Emanuel Libman, Dr. Currier McEwen, Dr. Walter W. Palmer, Dr. Henry Asloy Riley, Dr. Peyton Rous, Dr. Charles Hendee Smith, Dr. J. Bentley Squier, Dr. Mills Sturtevant, Dr. Homer F. Swift, Dr. Howard C. Taylor Jr. and Dr. I. Ogden Woodruff.

There is a central office, where each refugee physician is registered for the detailed examination of his credentials. (Information about any foreign physician may be obtained by writing to Mr. Charles H. Jordan, Secretary.)

There are advisory boards in each of twenty medical specialties whose function it is to evaluate and examine the personal and scientific qualifications of every refugee. These boards make confidential reports on the qualifications of each individual physician, which are filed in the central office.

Those who are passed by the advisory board are then given material aid by the National Coordinating Committee while studying for state board examinations.

A curriculum committee arranges lectures in various departments of medicine. Emphasis is placed on the broad cultural requirements of American medicine as well as on the factual information required for the licensing examinations. A program for clinical retraining is being prepared to fit certain specialists for general practice.

The committee seeks to secure voluntary assistantships, supernumerary internships and temporary clinic appointments for eligible physicians to assist them in their studies.

After passing their examinations, physicians are resettled in communities where there is a known shortage of medical care. This is done only after consultation with the local authorities and with local representatives of the medical profession.

THE SOLUTION

Community needs must be considered as well as the needs of the physician. Resettlement of qualified physicians in areas most in need of medical service, and therefore best able to absorb the newcomers, is the solution proposed by the Committee for the Resettlement of Foreign Physicians. To this end the committee hopes that a change can be effected in the regulations in a majority of states, which now either bar foreign physicians from practice or make it unduly difficult for them to obtain a license until they become citizens (a period of five years). These local regulations have been largely responsible for the concentration of these physicians on the Atlantic seaboard.

Unquestionably certain foreign physicians cannot and should not be permitted to practice here until they are thoroughly qualified. A few will never be able to meet American requirements. These, obviously, must be retrained outside the medical field.

The committee proposes, through an examining board of qualified physicians, to pass upon the personal or scientific qualifications of the incoming physicians. It will give no support to those who are adjudged to be unfit to practice in this country.

In this connection it is important to quote here from a statement of the Boston Committee on Medical Emigrés, as follows:

> After some ten months of experience, this Committee has learned:
> 1. That a substantial proportion of the medical refugees here and abroad are among the most talented members of the profession, in research and in clinical fields.
> 2. That existing prejudices against them derive most often from lack of contact and from fear that as aliens they are somehow undesirable. When they are given an opportunity to present themselves in person and have their professional achievements properly scrutinized, preconceived objections to them frequently soften or entirely disappear.
> 3. It appears likely that, if a thoroughgoing search of this country's unfilled medical needs were made, all of these men who have arrived or may arrive here and whom we consider competent would be absorbed without difficulty and to the distinct advantage of institutions and communities which otherwise go without the services they can provide.

It is the hope of the Committee for the Resettlement of Foreign Physicians that all members of the medical profession will cooperate in its work, to the end that the refugee physicians, who have no desire to compete with American physicians in congested areas, may be given an opportunity to exercise their profession, their skill and their training in areas where their services are most needed.

DAVID L. EDSALL, M.D., Boston.
Honorary Chairman, National Committee for the Resettlement of Foreign Physicians.

EFFECT OF SUNLIGHT ON BONE AS REPORTED BY HERODOTUS IN 450 B. C.

To the Editor:—In book III of Herodotus's history, in which he describes some of his travels in Egypt and Libya, an account is given of the Persian invasion of Egypt under Cambyses. Near the mouth of the so-called Pelusian Nile, the forces of Cambyses met the Egyptians under King Psammenitus in 525 B. C. Herodotus viewed the battle field about seventy-five years later. His attention was called to the striking difference in thickness and strength of the Persian and Egyptian skulls which were still lying on the surface of the ground. His explanation of this difference is interesting, being so far as I know the earliest recorded definite proof offered of the effect of sunshine in thickening and strengthening bone tissue. A translation of chapter 12 of book III, in as nearly the simple style of the original Ionic Greek as I can make it, runs as follows:

"I saw a great marvel of which I had heard from the natives of the country. The bones of those who fell on either side in this battle lay scattered separately. The bones of the Persians lay in one part of the field and the bones of the Egyptians in another, as the two armies had separately stood. The skulls of the Persians were so fragile that a mere pebble thrown at them would penetrate them. But those of the Egyptians were so strong that you could hardly break them with a stone. The cause of this, so the people said, and I readily agreed, is that from childhood the Egyptians shave their heads, and the bone is thickened by exposure to the sun. For the same reason they do not become bald. Of all races of men bald heads are rarest among the Egyptians. Such then is the reason for their strong skulls. And the reason why the Persians have weak skulls is that they cover their heads all their lives with felt hoods, called tiaras by the Persians. Such are the facts of the case. I noticed the same condition at Papremis in the skulls of the Persians slain by Inaros the Libyan."

E. V. WILCOX, Chevy Chase, Md.

"DIAPHRAGMATIC FLUTTER WITH SYMPTOMS OF ANGINA PECTORIS"

To the Editor:—It may be of interest to your readers to add a note as to the peregrination of the medical curiosity reported in THE JOURNAL by Dr. W. B. Porter March 21, 1936, page 992, and by Drs. Whitehead, Burnett and Lagen April 1, 1939, page 1236, as a case of diaphragmatic flutter with symptoms of angina pectoris.

The patient was brought to the Massachusetts General Hospital Oct. 27, 1937, by police ambulance with the identical clinical picture as described by the previous writers. He lay doubled up on his right side, moaning in pain and in no respiratory distress, with a pulse of 80 and a blood pressure 130/80. He was not perspiring and his color was good. A rapid flutter could be felt and ausculted over the precordium and abdomen, and could be seen as a ripple over the latter. Fluoroscopy showed a normally beating heart and a diaphragm that oscillated with about a 1 cm. excursion at a very rapid rate. An electrocardiogram showed a regular oscillation of the base line of 1 mm. amplitude at a rate close to 300 per minute. His temperature was normal.

He gave his name as Frank Crowley and his age as 65. On entry he presented us with a reprint of Dr. Porter's article, so I presume that is why he listed his occupation as a deep-sea diver, as he did in Richmond, Va. Numerous puncture marks were noticed over both antecubital spaces and his speedy release from all pain on entry after one-fourth grain (0.016 Gm.) of morphine and his subsequent loud demands for more gave some support to the belief that he was addicted to drugs. He proved a very irascible patient and demanded release at daylight on the morning after entry, which was speedily granted after threats to nurses. A psychiatrist thought that he was "queer" but probably not psychotic.

The next day he was picked up from the side of the road by a passing mortorist and was last heard from at the Framingham Hospital.

He was an excellent raconteur and his stories of inspecting the battleship *Maine* and the *Lusitania*, and of crossing the floor of the Red Sea in search of chariots were greatly appreciated.

EDWARD HAMLIN JR., M.D., Boston.

"SYPHILIS IN NORTH CAROLINA"

To the Editor:—In THE JOURNAL April 1, page 1260, appears a short comment entitled "Syphilis in North Carolina." In this article you raise a doubt as to the accuracy of the statement to which you refer and intimate that this statement was made for the purpose of securing federal funds for the control of syphilis in this state.

It is felt in this department that you have placed your own interpretation on these figures and evidently have arrived at an erroneous conclusion. You have mistaken the prevalence of syphilis for the incidence of syphilis. The 48,000 "new cases of syphilis" reported each year are not cases of "new" syphilis in the sense that the disease was acquired within the year in which it was reported. These "new" cases mean simply that they have never been reported before to this department. Many of them are cases of latent and late syphilis, but from a reporting standpoint they are new in that they have never previously been brought to the attention of this department by case report. From your comments you evidently interpreted the 48,000 cases to be those of newly acquired syphilis, acquired within the year in which they were reported. By actual count since Jan. 1, 1936, to Dec. 31, 1938, we have had reported to this department 164,254 cases of syphilis, and you can readily see that this is in excess of 4,000 "new" cases per month.

CARL V. REYNOLDS, M.D., Raleigh, N. C.
Secretary, North Carolina State Board of Health, and State Health Officer.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

POSSIBLE ACUTE CARBON MONOXIDE POISONING

To the Editor:—I was called to attend a patient in coma. The man, aged 24, was apparently healthy with no history of previous serious illness. He states that prior to becoming unconscious he operated the motor of a large truck in a garage with the doors open. In about a half hour he went to the second floor of the same building and looked at the clock, he expected a telephone call and definitely recalled the time. He then attempted to open a window but fell to the floor and recalled nothing until an hour and twenty minutes later, when I saw him. His face appeared flushed with no cyanosis except slight cyanosis of the lobules of the ears. He seemed to recognize me but was unable to speak. There was a definite flaccid paralysis of the left arm and leg. The deep reflexes of both legs and arms were exaggerated. There was *no ankle clonus nor was the Babinski reflex present*. The tongue deviated slightly to the left, and the left corner of the mouth was slightly raised. The right pupil was somewhat larger than the left, and this condition persists. Both pupils reacted well to light. The heart rate was 84 and there was arrhythmia. On admission to the hospital the temperature was 100 F. Despite the fact that I noted automobile fumes in the room and had all the windows opened, I thought that the patient had suffered a cerebral embolus. The blood pressure was 120 systolic, 82 diastolic. Within four hours the patient apparently completely recovered. He spoke clearly and the foregoing history was elicited. He could use the left arm and leg well. The pulse rose to 120 and the temperature fell to 98 F. and then to 97 F. in twelve hours. On the third day the pulse fell to 60 and then on the following day to 52. The blood pressure rose to 136/88. The pulse rate one week later was 72. The patient complained of headache shortly after recovering consciousness, but this persisted for only three days. Urinalysis revealed dark green urine, alkaline in reaction, with a specific gravity of 1.032, it was negative for sugar and albumin but the specimen contained 1 plus pus cells. The Kahn test gave negative results; examination of the blood showed red blood cells 4,990,000, hemoglobin 100 per cent, leukocytes 13,100, polymorphonuclear neutrophils 94 per cent, basophils 1 per cent, small lymphocytes, 4 per cent, large lymphocytes 1 per cent. Repeated urinalyses were negative for sugar. I have thought that this patient was overcome by carbon monoxide and have so stated. Are the foregoing symptoms and signs, together with the history, in harmony with such a diagnosis? The patient seems perfectly well but is somewhat anxious about having a recurrence of such an attack if not due to carbon monoxide poisoning. M.D., Pa.

ANSWER.—On the basis of the data submitted, which contain no real evidence of exposure to carbon monoxide other than the operation of a motor in a large garage with open doors, one cannot make a definite diagnosis of carbon monoxide poisoning. There are no statements as to the effects on other men in the garage at the same time and no data as to possible concentrations of carbon monoxide in the air. Under the circumstances of this accident, the conditions could readily be duplicated and such information obtained. If it could be shown that the air contained from 600 to 800 parts of carbon monoxide per million parts (or from 0.06 to 0.08 per cent), it would probably be proper to assume quite definitely that the illness was due to carbon monoxide. At the present time, far too many conditions are attributed to carbon monoxide without proper reference to the circumstances of exposure, and these should and generally can be proved.

If the symptoms are considered alone and if it is assumed that there is definite evidence that carbon monoxide was in the atmosphere, it is quite fair to believe that this is a case of carbon monoxide asphyxia. Almost any variety of acute neurologic disturbance can occur in carbon monoxide poisoning, and it is frequent that unconsciousness or some serious neurologic symptom is experienced when the patient attempts to move about actively, even though he may move to an atmosphere which is free of carbon monoxide. A man poisoned by carbon monoxide has been brought to the limit of his power to supply his tissues with oxygen from the blood. "He can stand no extra strain of any sort and, even when he regains consciousness, as may be the case when the blood carbon monoxide reaches 50 per cent of saturation, he still has so slight a margin of oxygen tension as to be quite unequal to activity of any sort without suffering instantly from oxygen lack. As Stadie and Martin (1925-1926) remark: 'Despite the presence in the blood of two or three times the amount of oxygen necessary for normal tissue function, profound anoxemia results in CO poisoning. This is due to an alteration of the shape and position of the oxygen dissociation curve causing a marked lowering of the partial pressure at which oxygen is available for tissue metabolism'" (Drinker, C. K.: Carbon Monoxide Asphyxia, New York, Oxford University Press, 1938. Stadie, W. C., and Martin, K. A.: The Elimination of Carbon Monoxide from the Blood: A Theoretical and Experimental Study, *J. Clin. Investigation* **2**:77 [Oct.] 1925). It is the usual rule that those who have had acute experiences due to carbon monoxide such as this recover completely and there is, of course, no reason why the condition should leave any threat behind in terms of possible further trouble.

URTICARIA AND MENSTRUATION

To the Editor:—Please give me some information as to the cause, treatment and prognosis of menstrual urticaria. The patient is about 25 years of age and ten months ago she had a cesarean section. Her menstruations are sometimes from four to seven weeks apart, but the history of menstrual urticaria is of several years' duration and the condition lasts from three to five days. H. C. WIGER, M.D., Rice Lake, Wis.

ANSWER.—It is presumed that by "menstrual urticaria" the inquirer has reference to urticarial attacks of a generalized nature (not localized to lesions on the skin in the proximity of the genitalia) occurring particularly in the premenstrual or menstrual periods. A history of urticaria or other allergic manifestations appearing solely or more frequently at that time is a common part of the patient's story. A number of medical articles dealing with that subject have been published. Almost without exception they are all clinical and based on consulting room observation. Intensive studies of a laboratory and experimental nature which might throw light on the association of these two factors, allergy and endocrine, are still lacking. It may be mentioned that there are other associations of a possible relationship between allergy and the endocrines. Some of these are exemplified by the tendency of allergic symptoms to be improved at puberty in the boy and to be aggravated in the same period in the girl, by the likelihood for allergic symptoms to diminish or vanish altogether during pregnancy and by the frequent change in the course of clinical allergy at the menopause.

Until the indicated experimental and laboratory work in the future provides a basis for a more specific and definite correlation of allergic symptoms and the menstrual cycle, this relationship will be regarded as a general one. According to the latter conception allergic symptoms are more apt to occur around the menstrual period just as they are more apt to occur following other emotional upsets, infections, exertion and thermal, mechanical and chemical stimuli. They are usually the precipitating factors rather than the specific causes in a patient who has an ever present allergy but is capable of being in allergic balance most of the time. In the case cited and in similar types there are three main methods by which one may achieve results: One is, of course, by a search for the basic underlying allergy. Another is by the use of rest, sedation and such other measures as may counteract the excitability of the nervous system. Finally, results sometimes may be achieved by endocrine therapy. The prognosis is fair.

SILVER PREPARATIONS FOR SINUSITIS

To the Editor:—Please discuss the treatment of sinusitis by the insertion of colloid silver tampons. M.D., Massachusetts

ANSWER.—The use of colloidal silver tampons in the treatment of chronic sinusitis is practiced extensively by otorhinolaryngologists in this country. In a recent questionnaire it was shown that approximately 90 per cent of specialists used some silver salt in treating diseases of the ear, nose and throat. Although practically every silver preparation has been used, the favorite one is mild protein silver (argyrol) usually in 10 per cent strength.

Colloidal silver preparations are said to be bactericidal, sedative to inflamed mucous membranes and stimulating to reparative powers. These are debatable points. It is true, however, that the colloidal silver preparations are mildly astringent and it is partly due to this property that they give symptomatic relief. Moreover, because of their colloidal state and their astringent property they do incite a profuse watery secretion from the mucous membranes which depletes the nasal mucosa, thus supposedly helping rid the nose and sinuses of bacteria and pus.

The more ardent proponents of the silver tampon treatment have formulated a routine of tampon insertion, designating types of cotton, applicators and position of the tampon. The latter, the "sphenoid" and "infundibulum" direction, is said to bring

the medication into contact with most of the sinus ostiums and is considered by some to be absolutely indispensable to the full success of the procedure. The tampons are left in place from thirty minutes to an hour and after removal the nose is flushed with some cool irrigating fluid.

Despite the popularity of this form of treatment there are many capable rhinologists who feel that it has no peculiar advantages over many other conservative methods of treating chronic sinusitis.

The bacteriostatic and bactericidal power of mild protein silver as investigated by Hilding, Cannon and Walsh, is so slight as to be of little clinical importance. The astringent effects can be achieved by many other drugs without too elaborate a technic of medication. Though mild protein silver has not been shown to be harmful to ciliary activity, the possibility of argyria, local or general, even though infrequent, must be kept in mind when one is using silver salts extensively.

POSSIBLE HEAT STROKE WITH APHASIA

To the Editor:—The following is the summary of a case of mixed aphasia which suddenly occurred coincidentally with what was diagnosed as "heat stroke." A white man aged 50, large, well developed and muscular, was working digging a basement for a school house. The day was hot, there was no air circulating in the pit and the sun was beaming overhead. At 1 p. m. the patient suddenly got faint and collapsed unconscious. His fellow workmen first thought he had fainted, but when he failed to revive he was taken to the hospital, where he had a subnormal temperature and excessive sweating, and where he remained unconscious for four days. On regaining consciousness he was found to have a motor aphasia, apraxia, paragraphia and partial auditory aphasia but no alexia. Right hemiparesis and right hemiapraxia were present. The tendon jerks were hyperactive on the right side. The spinal fluid was normal, the gold curve 00000000, the Wassermann reaction of both the spinal fluid and the blood was negative. The pressure was 150 mm. initially and also after 10 cc. had been removed. The cranial nerves were entirely normal, there being no evidence of arteriosclerosis of the retinal vessels. The blood pressure was 140 systolic, 90 diastolic. The peripheral arteries were soft. The patient shows no clinical evidence of cardiac, renal or other organic disease. The patient is suing for compensation insurance, none of which has ever been paid since the onset of his illness. Now the question arises Can heat stroke cause aphasic symptoms such as the aforementioned and can you cite such cases on record? I might add that the signs and symptoms have remained unchanged during the past six months since the onset of the illness.

W. L. SHARP, M.D., Anderson, Ind.

ANSWER.—It is improbable that the patient is suffering from heat stroke per se unless it can be shown that he was entirely well without cardiac, renal or any other organic disease prior to the onset of his coma and that following the exposure he developed a deep coma with a temperature of from 104 to 108 F. as well as an increased cell count in the spinal fluid. If this can be done it will be possible to establish a causal relationship between the heat of the sun and the present symptoms. If he had these symptoms (heat stroke), this is one of the rare cases in which recovery occurs. Most all patients with heat stroke or apoplexy die because of the high temperatures and dehydration despite all therapy. It seems peculiar that the man showed only those signs of a large softening or hemorrhage (embolus, hemorrhage or multiple thrombi) on the left side of the brain. In heat stroke there is a widespread ganglion cell damage which produces not only hemiplegia, paraplegia, ataxia and aphasia but also convulsions and psychosis. The article by Shattuck and Hilferty (*Am. J. Trop. Med.* **12**:223 [May] 1932) is recommended for perusal.

NARCOTIC ADDICTION AND HEREDITY

To the Editor:—I should like information concerning the effect of the use of morphine by the father, for a number of years previous to and at the time of conception, on the offspring. I also wish the same information where the father discontinued the use of morphine a few months prior to conception. I would also appreciate general information concerning morphinism and reproduction, especially relating to its effect on the offspring.

WALTER G. KLUGH, M.D., Hot Springs National Park, Ark.

ANSWER.—The problems and underlying reasons for the excessive use of narcotics and alcohol are the same. It is an escape mechanism from life's conflicts. Chronic morphinism has no true demonstrable pathologic picture. The nature of the disorder is mostly psychologic and not physiologic or pathologic.

Drug addicts can be divided into three groups: 1. The accidental addict, about 10 per cent, composed of normal individuals who develop the habit after the narcotic had been administered for the relief of pain for a period long enough to develop true withdrawal symptoms and who, when the narcotic is discontinued, do not resort to it again, after a successful denarcotization treatment. 2. The recidivists, about 30 per cent, composed of potential narcotic addicts with underlying nervous instability who, after once experiencing narcotic relief and sensation, are unwilling or think they are unable to stand the mental or physical distress which normal persons accept without demanding narcotic relief. 3. The psychopathic personalities, about 60 per cent, recruited from the large class of inadequates with serious underlying defects of personality who find the drug a panacea for their lack of ability to adjust themselves to life's conflicts; the latter group includes the ne'er-do-well type made up of life's misfits who, as a rule, in spite of the exaggerated and sensational news and police reports, are not vicious or dangerous criminals. Addicts make poor criminals. They have no will power, their judgment is defective, they cannot be trusted and they commit, as a rule, only petty crimes and are ostracized and looked down on by the more capable and dangerous criminals.

There is no evidence that the excessive use of morphine affects the germ plasm of ova or spermatozoa or that the offspring are injured by morphinism in the father. However, where the nursing mother is an addict, cases have been reported that when feeding at the breast was discontinued the baby exhibited withdrawal symptoms which were promptly relieved by an opiate.

The danger lies in the descendant's inheriting the unstable nervous system and personality defect of the parent rather than the effect of chronic morphinism.

ESTROGENIC SUBSTANCE FOR ACNE AND FACIAL HYPERTRICHOSIS

To the Editor:—Somewhere I have read that acne vulgaris and facial hypertrichosis have been successfully treated with folliculin ointment. Please explain how it works and where one may procure the ointment?

M.D., Ohio.

ANSWER.—The theory of the use of estrogenic substance for the treatment of acne and hypertrichosis is that both these disorders are due to lack of the estrogenic substance. This is no doubt true for some cases of hypertrichosis and may be part of the basis of some cases of acne vulgaris. Most dermatologists are willing to state that some hormone disturbance is behind dyscrasia of the sebaceous glands which results in acne, but what this disturbance is they are not able to say. Theodore Rosenthal and Raphael Kurzrok (Excretion of Estrin in Acne, *Proc. Soc. Exper. Biol. & Med.* **30**:1150 [May] 1933) found the estrogenic principle regularly present in the urine of normal women but absent from the urine of twenty-seven of the thirty-three women with acne vulgaris whom they tested.

Practical application of this theory to the treatment of acne vulgaris has not been conspicuously successful.

Templeton, H. J., and Truman, S. R.: Endocrine Therapy in Acne Vulgaris, *California & West. Med.* **48**: 337 (May) 1938.

In his discussion on the paper of Van Studdiford, C. Guy Lane cited a case of acne occurring at menstrual periods which had resisted x-rays but cleared up when amniotin was given for about seven months and remained clear without further medication. Earlier attempts to stop treatment had resulted in recurrence.

The results of the treatment of hypertrichosis in women is also unpredictable. In most cases no benefit is seen. Once in a while success is achieved for a while, but seldom is the result permanent. The chance of obtaining relief from the excessive growth of hair is much better when other symptoms of ovarian disturbance accompany the hypertrichosis.

While it seems that the use of estrogenic substance is justified in women with some signs of ovarian disturbance accompanied by hypertrichosis or acne vulgaris, especially the form which recurs at the menstrual period and clears up between the periods, it is certainly unwise to use such preparations indiscriminately. In view of the effect in young male rats, its use in boys with acne should be avoided. It is a drug with great and not fully explored potentialities. Its administration in ointment form has the disadvantage of indefinite dosage.

HYPERKERATOSES OF FEET

To the Editor —A woman aged 24, whose physical examination is otherwise negative, has had thick callosities of the soles, heels and toes of both feet for six years. A surgeon and a dermatologist in consultation agree that this is apparently a simple callosity. Various ointments, including cod liver oil and allantoin, as well as paring down, have been followed by prompt recurrence even when the patient was kept in bed for a month. Roentgen therapy (twelve treatments, details lacking) in a large New York hospital to the extent of producing a slough was otherwise ineffectual. Ultraviolet has been tried The patient has been saturated with vitamins A, B, C, D and G The roentgen necrosis is now healed Please help

JOSEPH M GROSS, M.D., Brooklyn

ANSWER.—Simple calluses are discrete overgrowths of the superficial part of the skin due to pressure or friction rub. Removal of the cause prevents recurrence of the callus. In view of the recurrence with the patient in bed, this would rule out the presence of a simple callus.

Hyperkeratosis, which corresponds to the description in this case, is an overgrowth of the outer layer of the skin which occurs on the plantar surface of the foot.

Hyperkeratosis is frequently a late stage of dermatomycosis. Treatment of the hyperkeratosis in such an instance would be the use of heliotherapy or Whitfield's ointment; 5 per cent salicylic acid in hydrous wool fat may be rubbed vigorously into the skin. Walking barefooted on dry sand is helpful if this is practical.

In addition, there is a hyperkeratotic condition of the skin which occurs in certain persons without known cause This type may be congenital. Inquiry should be made to ascertain whether arsenic has been used as medication, since this is sometimes a cause of hyperkeratosis. Roentgen treatment has been used in some cases with benefit, but most of these patients are best treated by thoroughly washing the foot with tincture of green soap, which softens the skin. This is followed by an application of 5 per cent salicylic acid in hydrous wool fat, which is rubbed vigorously into the skin several times a day.

HEMORRHAGE AND LEUKEMIA

To the Editor —In a case of lymphatic leukemia, with the patient in fair condition and of plethoric type, what would be the effect of removal of a large quantity of blood (blood letting)? How long is the time of blood restoration? Which constituents of the blood are first restored? Are the erythrocytes or leukocytes first regenerated? Has this been given any scientific study as to extent or location of faulty regenerative function of the hematopoietic cells?

A. G. LEE, M D , Texarkana, Ark.

ANSWER —Although there are no data available on the effect of venesection in leukemia, large spontaneous hemorrhages occur which produce the same effect. Following such an occurrence, red cell and hemoglobin regeneration is slow—often there is no regeneration, especially in the acute forms of the disease. This poor response is probably due to the fact that the red cell forming tissue is already overtaxed In several observed cases extensive hemorrhage did not affect the white cells appreciably.

No literature is available on the use of venesection as a test in leukemia. However, the cause of the anemia in leukemia is not settled, being variously thought to be due to malfunction of the marrow or to increased peripheral destruction.

POISONING FROM SELENIUM

To the Editor:—Kindly give me a brief description of so called poisoning by selenium fumes and the treatment.

M D., New York

ANSWER —Acute or chronic poisoning by selenium may be produced by inhalation of volatile selenium compounds or seleniferous dusts. In animals inhalation of moderately high concentrations of hydrogen selenide (H_2Se) produced fatty metamorphosis of the liver, accompanied later by hypertrophy of the spleen At lower concentrations of hydrogen selenide, animals show less marked liver and spleen damage. Numerous studies have shown the toxic properties of selenium on ingestion or injection of its compounds. In general the site of greatest injury from absorption of selenium compounds is the liver, spleen and kidneys.

In man the symptoms following prolonged absorption of selenium may include pallo [illegible] disturbances, garlic odor of the breath and [illegible] of the nose and throat (rose cold), coating of the tongue, and metallic taste in the mouth. Selenium in the urine is conclusive evidence that absorption of selenium has occurred. Analysis of a morning specimen of urine for selenium is suggested as a diagnostic procedure.

To prevent further absorption of selenium is the first step in the treatment of chronic selenium poisoning. The treatment is symptomatic; some authors suggest the use of a high carbohydrate diet, with increased water intake, as excretion is predominantly renal.

TUBERCULOSIS AND CAISSON DISEASE

To the Editor —A man aged 38 suffered an attack of caisson disease in March 1936, from which he made an almost complete recovery Examination of his lungs at that time did not reveal any pathologic condition and no x-ray examination was made. In March 1937 a diagnosis of active pulmonary tuberculosis (positive sputum and roentgenograms) was made. He began to cough about a month before the roentgenograms were taken. Is there any possible connection between the tuberculosis and the caisson disease? Is there any literature on this subject?

M D , New Jersey

ANSWER.—There is no logical explanation of a relationship between the attack of caisson disease which the patient suffered in March 1936 and the presence of active pulmonary tuberculosis in March 1937. As pulmonary tuberculosis frequently is not detected by physical examination and since x-ray films were not made, it is possible that pulmonary disease was present in a presymptom stage at the time he had caisson disease. Often chronic pulmonary tuberculosis can be located by x-ray films several years before significant abnormal physical signs or symptoms make their appearance. Therefore it is possible that x-ray examination in March 1936 would have revealed evidence of the disease.

On the other hand, it is possible that tuberculosis was not present in March 1936 and that the patient became infected subsequently to that date, since many persons now contract their first infections in adult life. No mention is made of a tuberculin test having been administered at the time of or subsequent to the attack of caisson disease. If this was done, and the patient was a nonreactor at that time, there is excellent evidence that the tuberculosis is of recent origin Although the time is short for the development of chronic pulmonary tuberculosis from a recent infection there is occasionally such an occurrence. However, with the evidence presented there would not appear to be any association between caisson disease and tuberculosis.

RABIES PROPHYLAXIS

To the Editor —A recent outbreak of rabies resulted in scores of people presenting themselves for preventive treatment Their contacts varied from ordinary petting of rabid animals to actual bites One department in the area gave treatment to every one who had had any contact at all, whereas the other department required an actual bite of more than trivial extent before Pasteur treatment was started Must a skin wound from the bite of a rabid animal be of subcutaneous depth or more before Pasteur treatment is indicated? Do small, superficial breaks in the skin indicate treatment if the patient has had contact with a rabid animal?

JOHN M. COLLINS, M D , Seattle

ANSWER.—In the treatment of a person who may have been bitten by a rabid animal, the guiding principle is always safety first. Take no chances! The answer to the first question is No Any wound made by the bite of a rabid animal, no matter how insignificant, may admit the infection The answer to the second question is Yes in case it is possible that the break in the skin was made by the bite of a rabid animal.

COPPER IN DRINKING WATER

To the Editor.—Will you please advise me as to whether or not any toxic effects could result from using drinking water which contains 0.65 part of copper per million parts of water?

ARTHUR H. LONDON JR , M.D , Durham, N. C.

ANSWER.—The United States Treasury Department standard for water supplies to be furnished for drinking and culinary purposes by interstate carriers requires that the copper content of the water shall not exceed 0.2 part per million In recent years there has been some criticism of this standard by biochemists and physiologists, claiming that it is too low and that harmful effects may not result if the copper content is as high as 1 part per million. Experience with the physiologic effects of copper in the light of its more liberal use in water service connections and for control of algae in the public water supplies seems to indicate that the official standard is quite conservative.

GLASSES FOR PROTECTION AGAINST ULTRAVIOLET RAYS FROM A QUARTZ BURNER

To the Editor:—Do ordinary glass or polaroid glasses give adequate protection against ultraviolet rays directed into the face with the eyes open from a Hanovia mercury vapor quartz burner? What is the lens in the goggle furnished by the manufacturer? The representative is unable to tell me.

M.D., New York.

ANSWER.—Ordinary glass and polaroid glasses do give adequate protection against ultraviolet rays directed into the face with the eyes open with any quartz burner emitting ultraviolet rays. The polaroid glasses, however, are rather expensive and there is no point in using them for protection against ultraviolet rays, as ordinary winlow glass serves the same purpose.

Glass in goggles ordinarily used when taking ultraviolet radiation treatments are of various styles and usually are colored merely to soften the glare of the light. There are glass preparations on the market for protection against the effects of screening out infra-red radiation as well as ultraviolet radiation.

CHILDBIRTH AND OBESITY

To the Editor:—What would be the proper procedure for delivery in the following case? A negro woman 29 years old and weighing 325 pounds (147 Kg.) had one child after a difficult labor sixteen years ago and another stillborn child nine years ago. At both previous pregnancies her weight was under 200 pounds. She is at term. The question has arisen whether this woman should be delivered by cesarean section without previous test of labor or should be allowed to go into labor and the case handled from then on according to indication.

M.D., Indiana.

ANSWER.—A cesarean section in a patient weighing 325 pounds is a formidable procedure. It necessarily carries with it a considerable risk for the mother. The query does not state that the previous stillborn children were the result of difficult labors. The labors may not have contributed to the fetal deaths. Unless some unusual complication arises, the safest procedure is to allow the patient to go into labor and deliver her through the birth canal. The rapid increase in her weight need not necessarily contribute to a more difficult natural delivery.

ORAL IRON MEDICATION AND CONSTIPATION

To the Editor:—What method or methods may be used to prevent the constipation so frequently caused by oral iron medication?

E. N. MURRAY, M.D., Camden, N. J.

ANSWER.—Oral iron medication usually causes constipation in persons who already have such a tendency. Sometimes the constipating effect seems to be worse when small doses are given. Ferrous sulfate and iron and ammonium citrates given on an empty stomach between meals in 0.2 Gm. (3 grain) and 2 Gm. (30 grain) doses three times a day respectively are frequently less costive than other preparations. If this fails, the usual treatments for constipation must be tried.

SUPERNUMERARY FINGERS AND TOES

To the Editor:—Please state what you consider the best time in life to operate on supernumerary fingers and toes.

M.D., Ontario.

ANSWER.—In general it would be wise to remove supernumerary fingers and toes early in life, in fact as soon as the parts involved are well enough developed to make an accurate surgical removal possible after a careful study of the roentgenograms. Sometimes these extra digits are attached by separate joints, sometimes one joint suffices for both, and therefore the amputation must avoid impairment of the function of the adjacent finger or toe. In general this type of plastic surgery should be done about the end of the first year.

VAGINAL ABSORPTION

To the Editor:—On page 173 of the January 14 issue of THE JOURNAL the question "Is there any absorption from the vaginal mucosa?" is answered "There is no absorption from the intact vaginal mucosa. There can be absorption from a damaged mucosa. It is not probable that absorption in such a manner occurs often enough to be of practical importance." Absorption of the estrogens from the vaginal mucosa is well known. Serious poisoning and fatalities have been all too frequently reported after the use of mercury bichloride for vaginal douches. In addition there is the study by Macht (*J. Pharmacol. & Exper. Therap.* **10**: 509 [Jan.] 1918) in which it is stated in the conclusions: "It has been shown that a large number of drugs and poisons . . . alkaloids, inorganic salts, esters and antiseptics can be and are easily absorbed through the vaginal wall."

WALTER MODELL, M.D., New York.

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, May 6, page 1857.

Colorado January Report

Dr. Harvey W. Snyder, secretary, Colorado State Board of Medical Examiners, reports the written examination held at Denver, Jan. 4-6, 1939. The examination covered eight subjects and included 161 questions. An average of 75 per cent was required to pass. Three candidates were examined, all of whom passed. Four physicians were licensed by endorsement on January 3. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Northwestern University Medical School		(1938)	89
Osteopaths *			82, 86

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Rush Medical College		(1937)	N. B. M. Ex.
State University of Iowa College of Medicine		(1926)	Iowa
St. Louis University School of Medicine		(1936)	Illinois
Baylor University College of Medicine		(1926)	Texas

* Licensed to practice medicine and surgery.

Book Notices

The Treatment of Fractures. By Charles Locke Scudder, A.B., Ph.B., M.D., Consulting Surgeon to the Massachusetts General Hospital, Boston. Eleventh edition. Cloth. Price, $12. Pp. 1,208, with 1,717 illustrations. Philadelphia & London: W. B. Saunders Company, 1938.

The treatment of fractures forms a more important part of surgical practice today than ever before because of much reckless automobile driving and the ever increasing mechanization of industry. In the twelve years since the previous edition of this book there have been many advances in the diagnosis and treatment of fractures, making it necessary for the author to rewrite his material completely. He has deleted all obsolete methods of diagnosis and treatment and added hundreds of new illustrations. Dr. Scudder personally approves the opinions expressed by the twenty other contributors to the volume, men actually engaged in doing the procedures about which they have written. He recognizes the importance of adequate first aid treatment and proper transport, factors which the general practitioner must master. There are forty-seven chapters; however, the size of the book remains convenient. It closes with a chapter on the medicolegal aspects of fractures.

The Essentials of Modern Surgery. Edited by R. M. Handfield-Jones, M.C., M.S., F.R.C.S., Surgeon to Out-Patients, St. Mary's Hospital, London, and A. E. Porritt, M.A., M.Ch., F.R.C.S., Surgeon to His Majesty's Household. Cloth. Price, $9. Pp. 1,126, with 501 illustrations. Baltimore: William Wood & Company, 1938.

This book succeeds in its attempt to present the essentials of modern surgery in concise form for both students and practitioners. While it represents the work of fifteen authors, who are responsible for individual chapters, the chapters contributed by the senior author are especially fine. The numerous and instructive illustrations are unsurpassed in any similar volume. In arrangement the book resembles many current volumes in the same field, beginning with an entirely adequate treatment of the pathology of inflammation, infections and the principles of surgical technic and then passing on to regional surgery. The text is lucid, interesting and in general authoritative. However, an American reviewer is surprised to find in the chapter on anesthesia considerable discussion of chloroform but no mention of ethylene or of some of the more recent inhalation anesthetic agents. A more adequate discussion of diseases of the biliary tract and of cholecystography seems desirable. No mention is made of the use of the gastroscope and its place in the diagnosis of gastric lesions. More serious is the omission of any discussion of the problems of water balance, dehydration, and demineralization in preoperative and postoperative treatment and the significance of these factors in acute intestinal obstruction, acute dilatation of the stomach and high intestinal fistulas. These are minor criticisms, however, and both the authors and the publisher are to be highly commended for the production of this book.

Clinical and Experimental Investigations in Agranulocytosis with Special Reference to the Etiology. By Preben Plum. Denne Afhandling er af det lægevidenskabelige Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad, København. Paper. Pp. 410, with 125 illustrations. London: H. K. Lewis & Co., Ltd.; Copenhagen: NYT Nordisk Forlag, Arnold Busck, 1937.

Most of this volume is devoted to the etiology of granulocytopenia. It is the most comprehensive and accurate compilation of data concerning that disease which has yet appeared. There are twelve chapters, a section of photomicrographs and records of 114 cases of agranulocytosis and other leukopenic diseases, all of which were observed in Denmark by the author or his colleagues. These chapters are followed by a list of drugs incriminated in the production of the disease, a summary, a summary in Danish, and finally a bibliography of 422 references incorporating the literature of the world. As stated in the introduction, the author compiled this work under a fellowship from a Danish fund for medical research and was aided by financial grants from other scientific agencies of Denmark. Therefore it can be considered to be accurate and scientific.

The first chapter considers the history of the disease, and early sporadic cases are cited. Plum concludes that the disease probably did not exist before the report of Schultz in 1922. There is then a thorough discussion of the terminology, geographic distribution, seasonal incidence, sex and age incidence and occupational frequency. Just as in the United States, the disease in Denmark has occurred more frequently in physicians, nurses and others closely associated with the medical profession. In about fifty pages there is an excellent summing up of the clinical symptoms, hematologic signs, pathologic changes and results of laboratory studies. Data from the world literature are presented, and the reports of the ninety cases studied in Denmark are included. Nearly eighty pages is then devoted to the etiology of agranulocytosis, and in this section is found the most interesting material. The author considers the various etiologic concepts that have been presented, including the role of infections, the various predisposing factors, the influence of the menstrual cycle, the role of allergy, the effects of such agents as arsphenamine, benzene, arsenic, bismuth and gold preparations and, finally, the role of aminopyrine. There is then presented an accurate and chronologic record of the development of the theory of causation by drugs, beginning with the report of Kracke in the United States, who is given priority for the development of the concept. The author summarizes the cases reported of granulocytopenia occurring after the administration of aminopyrine, including experimental work with both human beings and animals, and includes his own extensive experiments. There is a brief discussion of the role of other drugs, including the barbituric acid preparations, novaldin, antipyrine, acetanilid, acetophenetidin, dinitrophenol, cinchophen, quinine, neostibosan and sulfanilamide. He states that since the probable etiologic significance of aminopyrine was recognized in Denmark the consumption of the drug has markedly decreased and that there has been a remarkable parallel between the incidence of the disease and the consumption of the drug to the extent that in 1936 the disease had practically disappeared. He concludes that it may be safely assumed that, as far as Denmark is concerned, aminopyrine is in all probability the main etiologic factor in agranulocytosis. He then discusses the pathogenesis, emphasizing the belief that the clinical symptoms are preceded by the hematologic changes and that the infectious processes result from loss of cellular resistance. The final four chapters deal with the diagnosis, differential diagnosis, course, prognosis and treatment. He discusses the merits of treatment with nucleic acid products including pentnucleotide, liver extract, transfusions, x-rays and other measures. A note of pessimism is sounded, for "according to our present knowledge of the etiology of agranulocystosis the therapeutic methods generally employed do not appear particularly expedient" and "the rational thing is to direct our therapeutic efforts against the provoking agent." He stresses the value of

prophylaxis and emphasizes that the most valuable measure in the control of the disease is to reduce the consumption of aminopyrine.

The twenty-six colored illustrations are excellent photomicrographic reproductions of the various mature and immature blood cells, and the black and white ones are mainly of the bone marrow in agranulocytosis. This work is available in both English and Danish. It has been executed with meticulous care and with a high degree of accuracy by one who obviously is a careful worker. It represents an authoritative source of material for all those interested in agranulocytosis and other leukopenic diseases.

Proceedings of the Fourth Conference on Psychiatric Education Undergraduate Instruction, Baltimore, Maryland, April 8-10, 1936. Paper. Pp. 345. New York City: The National Committee for Mental Hygiene, Inc., Division of Psychiatric Education, 1938.

In April 1936 the Fourth Conference on Psychiatric Education was held in Baltimore with Adolph Meyer in the chair. The present volume is a report of the proceedings of this conference and is an extremely comprehensive survey of the subject of psychiatric education. Many reports are included which discuss how much of the medical school schedule is devoted in various universities at the present time to the presenting of psychiatric material to the student. Papers were read in which the ideal curriculum in psychiatry for medical students was considered, and such features as the need of premedical psychology courses and the relationship of other parts of the medical curriculum to psychiatry were discussed in some detail. Considerable attention was devoted to the matter of how psychiatry should be taught, how the class work should be divided, the purpose of ward walks and the need for special training in the teaching of psychiatry. About a third of these proceedings is allotted to an appendix, which deals with the psychiatric course presented at the Johns Hopkins Hospital. There are classifications of mental disease along the lines of those in use at the Johns Hopkins University School of Medicine, and forms for history taking and recording are also shown. Also included in the appendix are several papers, chiefly by Dr. Meyer, which were not read at this conference but which treat of various aspects of psychiatry.

Traité de chirurgie orthopédique. Publié sous la direction de L. Ombrédanne et P. Mathieu. Secrétaires de la rédaction: M. Lance, G. Huc et P. Padovani. Tome I. Physiologie, pathologie et therapeutique. Cloth. Price, 300 francs. Pp. 902, with 433 illustrations. Tome II. Physiologie, pathologie et therapeutic générales (fin.) Rachis; membre supérieur. Half-cloth. Pp. 903-1921, with illustrations. Tome III. Deuxième partie: Rachis; membre supérieur (suite et fin). Cloth. Price, 300 francs. Pp. 1919-2875, with illustrations. Tome IV. Troisième partie: Bassin; membre inférieur. Half-cloth. Price, 300 francs. Pp. 2873-3778, with illustrations. Tome V. Troisième partie: Rachis; membre inférieur (suite et fin). Half-cloth. Price, 300 francs. Pp. 3777-4482, with illustrations. Paris: Masson & Cie, 1937.

This set of five volumes is the finest material on orthopedic surgery that has come from France. It reflects the knowledge of French orthopedic surgeons and general surgeons interested in bone and joint and related lesions. The contributors were chosen with great care, and they have done themselves, both individually and collectively, great honor. Some of the most notable are Ombredanne, Mathieu, Lance, Huc, Padovani, Calvé, Delahaye, Ducroquet, Fontaine, Ferdet, Inglerans, Lamy, Lasserre, LeDoux-Lebard, LeFort, Leriche, Leveuf, Mouchet, Nové-Josserand, Policard, Ponzet, Rendu, Rocher, Roederer, Sorrel, Sorrel-Dejerine and Tavernier. Volume I treats congenital malformation of the extremities, the skeletal system, lesions of bones, diseases of joint and surgical procedures on joints, diseases of muscles, tendons and aponeuroses, and lesions of the skin. Volume II deals with diseases of the nervous system, including spastic paralysis, infantile paralysis and wounds of nerves, as well as lesions of the blood vessels of interest to the orthopedic surgeon, diseases of the blood, diagnostic roentgenography in orthepedic surgery, apparatus, including splints and braces, plaster of paris and celluloid, treatment in general of wounds, kinesitherapy, physical therapy and climatotherapy. The second part of this volume discusses the spine and all its lesions. Volume III contains a discussion of tumors of the vertebra, unusual diseases, the shoulder girdle and all its lesions, the thorax, the scapula, the shoulder, the arm, the elbow, the forearm, the wrist and the hand. Volume IV deals with the pelvis, the hip, the thigh and the knee from the standpoint of congenital defects and infectious diseases. Volume V deals with the leg, the ankle joint and the foot, amputations, apparatus of all types, paralysis of the upper extremities, operative technic and apparatus for paralysis of the upper extremities and for the lower extremities, and the procedures for equalization of the length of the lower extremities. The text, composition and illustrations are excellent. The collaborators are unfamiliar with or unwilling to accept the work of surgeons in other countries. There is an occasional reference to Italian and German literature but few to that of the English speaking countries. The work is encyclopedic; it cannot be recommended to the individual English reading orthopedic surgeon but is a valuable reference work.

Archiv und Atlas der normalen und pathologischen Anatomie in typischen Röntgenbildern. Röntgendiagnostik der Gelenke mittels Doppelkontrastmethode. Von Dr. J. Oberholzer, Chefarzt am Kantonalen Krankenhaus Wallenstadt. Mit Vorwort von Dr. med. E. Bircher, A. Spitaldirektor Aarau. Fortschritte auf dem Gebiete der Röntgenstrahlen, Ergänzungsband LVI. Herausgeber: Prof. Grashey. Paper. Price, 23 marks. Pp. 128, with 134 illustrations. Leipzig: Georg Thieme, 1938.

The author discusses diagnostic roentgenography of joints by means of a double contrast method. The technic of the injection of various joints by the contrast method and the x-ray technic are effectively demonstrated. The discussions and illustrations, especially of the knee joint, are excellent and offer a fine method of precise diagnosis of interesting and often difficult problems.

Analysis of Parergasia. By Gladys C. Terry, Research Associate, Neurological Institute of New York, Columbia University, New York, and Thomas A. C. Rennie, M.D., Associate in Psychiatry, Phipps Psychiatric Clinic, Johns Hopkins University, Baltimore. With an introduction by Adolf Meyer, Henry Phipps Professor of Psychiatry, Johns Hopkins University, Baltimore. Nervous and Mental Disease Monograph Series No. 64. Boards. Price, $4. Pp. 202. New York: Nervous and Mental Disease Publishing Company, 1938.

Seventy-seven cases of parergasia or schizophrenia from the basis for the present volume. A mass of data is arranged according to the life experience chart of Adolph Meyer. A tremendous amount of material is presented and yet a purely descriptive use is made of it. The parergastic subject's life defeat is based on poor constitution and personality traits which cause failure in adaptation to life situations. However, to accept life situations which impinge on the individual even in the early years as dynamic factors is the great defect of the meyerian psychobiology. It gives, in other words, lip service to the term dynamic and treats it purely descriptively. The material is so organized in a summarized descriptive form that no truly dynamic reconstruction could be achieved. Life experiences are stressed as important to the individual's fate yet their meaning in terms of the individual is ignored. The earliest infantile situations are virtually overlooked and the patient is considered as crushed by relatively late experiences impinging on a psychobiologic unit poorly prepared for them. What makes him unable to live through the multifarious experiences which are not so specific for his life? In this regard the followers of Meyer ignore the earliest infantile experiences which in their effects on the personality may cause truly dynamic alterations and prepare the way for the future failure in adjustment. These earliest interactions are so completely overlooked in this book that a tremendous amount of work becomes valuable only in a descriptive sense.

The Functions of Human Voluntary Muscles. By Norman D. Royle, M.D., Ch.M., F.R.A.C.S., Senior Orthopaedic Surgeon, Lewisham Hospital, Sydney. Cloth. Price, 3s. 6d. Pp. 42, with 11 illustrations. Sydney & London: Angus & Robertson Limited, 1938.

Dr. Royle developed a remarkable control of the individual muscles of his own body, thus acquiring a unique knowledge of the actions of certain muscles. This knowledge was the basis of a series of lectures in the department of anatomy at the University of Sydney, Australia, which in turn were the basis of this book. He discusses the movements of the vertebral column, jaws, shoulder girdle, upper limbs and lower limbs and emphasizes the importance of a knowledge of the formation as well as of the attachments and nerve supply of a muscle in determining appropriate treatment. Various methods of approach in ascertaining the formation of muscles, namely

anatomic, pathologic, electrical and physiologic methods, are described, and the principal or prime mover, reverse action, fixation muscles and synergic action are discussed. At first thought this book seems elementary, but it is well worth the time of any physician and especially the orthopedic surgeon.

Röntgendiagnostik der Knochen- und Gelenkkrankheiten. Von Professor Dr. Robert Kienböck. Heft 5 (Abteilung Gelenkkrankheiten): Rheumatoide Gelenkstuberkulose. Paper. Price, 60 marks. Pp. 451-1049, with 610 Illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1938.

This elaborate and comprehensive book on rheumatoid tuberculosis of the joints, volume 5 in a series on the x-ray diagnosis of bone and joint diseases, is divided into chapters on tuberculosis of the joints of the hand, the shoulder, the foot, the knee, the hip, the sacro-iliac region and the vertebrae. The second part deals with multiple lesions, including diseases, Heberden's nodes and mono-articular infections. There are several excellent illustrations of rhizomelic spondylosis with the bamboo pole appearance involving the cervical thoracic and lumbar vertebrae. The author discusses 378 cases and presents an extensive bibliography under eighteen headings. This fine volume is chiefly a reference book, highly technical and of value to those who read German easily.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Disability from Displacement of Fifth Lumbar Vertebra. — Donker, a man weighing about 200 pounds (90.7 Kg.), in the course of his employment Jan. 3, 1936, fell on his back and could not continue working. His legs felt numb and he had pains in his legs and back. He was taken to a physician in Sioux City for treatment but the pains persisted after several weeks of treatment. The physician then removed the patient's coccyx. The last week in April the physician released the patient, although at the time the patient complained of a burning sensation up and down his spine and numbness in his legs. Another physician, consulted about May 20, prescribed a brace for the lower part of the body and rendered treatment until August 19, but the pains continued to grow worse. On the last date named the workman entered the Veterans' Hospital in Lincoln, Neb., where he was kept in a cast for five weeks and was given a brace, his tonsils were removed and some teeth were extracted. After his release from the hospital, November 3, he instituted proceedings under the workmen's compensation act of Nebraska. At the trial he testified that he had very little use of his legs and was forced to wear the brace continuously, that his legs were numb and that he suffered a burning sensation of the spine and hip pains. The trial court awarded compensation for temporary total disability and the employer and his insurance carrier appealed to the Supreme Court of Nebraska.

The only questions for determination by the Supreme Court were the extent of the injuries suffered by the workman and the nature of the resulting disabilities. A physician who personally supervised the treatment given the workman at the Veterans' Hospital and who examined him during the month preceding the trial testified that in his opinion Donker was permanently and totally disabled. As to the condition of the lower portion of Donker's spine, there was expert testimony that the fifth lumbar vertebra was displaced forward so as to be no longer in line with the sacrum and that the space between the two was wider than normal. That condition, the witness testified, might have been present before the injury, might have been aggravated by the injury or might have been caused entirely by the injury. Donker's family physician, who attended him after his release from the Veterans' Hospital, testified, from the results of examinations made including the use of roentgenograms and his previous knowledge of the patient's condition, that the fall on January 3 would be sufficient to cause the injuries from which he suffered, that in his opinion the workman's disability was due wholly and entirely to the fall and that the workman was totally and permanently disabled.

The Supreme Court concluded that the finding of the trial court that the workman was suffering from at least temporary total disability was clearly established by the evidence. It was undisputed that prior to January 3 Donker was an able bodied laborer, capable of continuously performing hard work without ill effects. After that date his condition changed markedly. The only explanation offered for that change by the defendant was that the workman was a malingerer. But the evidence, the court thought, preponderated against that conclusion.

Taking into consideration all the evidence, the Supreme Court concluded that the judgment of the trial court awarding compensation was justified. The judgment was therefore affirmed. —*Donker v. Central West Public Service Co. (Neb.), 280 N. W. 168.*

Vancouver Medical Association Summer School, Vancouver, B. C., June 6-9. Dr. W. W. Simpson, 203 Medical Dental Bldg., Vancouver, B. C., Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Evaluation of Heart Volume Determinations by the Rohrer-Kahlstorf Formula as a Clinical Method of Measuring Heart Size. W. J. Comeau and P. D. White, Boston.—p. 158.
*Effects of Alkalosis and of Acidosis on the Human Electrocardiogram. P. S. Barker, Ann Arbor, Mich.; E. L. Shrader and Ethel Ronzoni, St. Louis.—p. 169.
Studies on Mercurial Diuresis: II. Immediate Effect on Venous Blood Pressure. I. F. Volini and R. O. Levitt, Chicago.—p. 187.
Plethysmographic Studies of Peripheral Blood Flow in Man: I. Criteria for Obtaining Accurate Plethysmographic Data. D. I. Abramson, H. Zazeela and J. Marrus, Cincinnati.—p. 194.
Id.: II. Physiologic Factors Affecting Resting Blood Flow in the Extremities. D. I. Abramson, H. Zazeela and J. Marrus, Cincinnati.—p. 206.
Use of Magnesium Sulfate in Measurement of Circulation Time. M. Bernstein and S. Simkins, Philadelphia.—p. 218.

Effects of Alkalosis and Acidosis on Electrocardiogram.—Barker and his co-workers observed pronounced flattening of the T waves in a patient with hysterical overventilation and tetany. This prompted an experimental investigation of the effects of alkalosis and acidosis on forty electrocardiograms of seven human volunteers. Alkalosis produced by voluntary overventilation or by the ingestion of sodium bicarbonate was accompanied by a reduction in the amplitude of the T wave. Acidosis produced by exercise or by the ingestion of ammonium chloride was accompanied by an increase in the amplitude of the T wave. While the clinical application of these observations is probably quite limited, they may offer an explanation for occasional electrocardiographic changes not otherwise understood.

Effect of Calcium on Uterine Contractions.—Danforth and Ivy find that calcium is necessary for the maintenance of the tone, contractility and coordinated activity of the postpartum uterus of the dog and rabbit. When the available calcium is sufficiently reduced by the use of soluble sodium hexametaphosphate, uterine contractions do not occur. The oxytocic action of pitocin, ergonovine and histamine is potentiated by calcium. Doses of pitocin, ergonovine and histamine, which are normally adequate for a uterine response, are ineffective when the available calcium is diminished.

Etiologic Factors in Sterility.—During the last four years Kotz and Parker studied completely 150 patients with the primary complaint of sterility. The etiologic factors in sterility in the female are grouped as (1) constitutional abnormalities, (2) organic pelvic pathologic conditions, (3) closed tubes and (4) endocrine abnormalities. In the male sexual incompetence is usually the etiologic factor. In every sterile couple a multiplicity of factors were operative. Absolute sterility was always due primarily to a specific organic pelvic pathologic condition. Relative sterility was usually due to many less serious factors. The secondary sterilities, as judged from their past histories, had a lowered fertility irrespective of the factors operative at the time of the examination. In the relative sterilities, pathologic changes in the pelvis, closed tubes, endocrine factors and male incompetence were the causes of the sterility, the significance of each being dependent on the severity of the condition and its association with other factors. Sterility due to a single fault was rare. Constitutional factors were not found to be the cause of sterility in any case. Endocrine factors were found to be important in the production of sterility. Blood hormone tests are valuable in determining the etiology of ovarian failure. The endometrial biopsy is the most accurate method of determining the type and degree of ovarian failure. There is no specific routine treatment for sterility. The one aim is to correct as many faults as possible. Of the 120 patients with relative sterility, thirty received no treatment. Twelve patients did not follow the treatment for the prescribed time. Seventy-eight patients with relative sterility were treated. There have been forty-one pregnancies, thirty-five of which were normal, five were miscarriages and one was ectopic. There were no instances of fetal abnormalities. Thirteen cases were considered failures and twenty-four patients are still under treatment. Of the thirty cases of absolute sterility the specific causes were as follows: The tubes had been previously removed in four, a large fibroid uterus was present in four, there was one case of bilateral chocolate cysts of the ovaries and one of sclerotic

ovaries, there were thirteen instances of closed tubes which could not be opened, pelvic inflammatory disease with closed tubes accounted for five cases and there were two cases in which male incompetence was the only cause.

Trichomonas Bartholinitis and Skeneitis.—According to Shelanski and Savitz, Trichomonas vaginalis has been demonstrated in Bartholin and Skene's glands and is a specific factor in producing bartholinitis and skeneitis. The presence of Trichomonas vaginalis in these glands is the source for reinfestation in recurrent cases of Trichomonas vaginalis vaginitis. Injection of the glands with a 1 per cent solution of silver picrate has been found useful in treating this infestation.

Common Wart in Etiology of Conjunctivitis and Keratitis.—De Rotth summarizes his experience with ocular diseases caused by common warts of the eyelids, which he first described in 1933. He has encountered seven cases of unilateral conjunctivitis, mostly of the subacute form, and three cases of keratitis of different types in connection with these warts. An additional case of bilateral conjunctivitis is reported in which warts occurred on the lids of both eyes. The virus of the wart is considered to be the etiologic factor in these cases. This view is based on the conformity of the following facts: the unilateral appearance; the involvement of the superficial layers of the eye, which points to an exogenous factor; the resistance toward the usual treatment; the presence of one or several warts on the margin of the eyelid of the diseased eye; the quick recovery after the removal of the warts, and the analogy to molluscum conjunctivitis. On the basis of these facts, the author believes that all inclusion diseases of the skin are able to attack the eye.

Ocular Importance of Sarcoid.—Walsh cites several cases which give, he believes, further clinical and histologic evidence that uveoparotid fever and sarcoid are closely related diseases. The protean ocular manifestations of uveoparotid fever and sarcoid are exemplified by the case reports. Although ocular tissues were involved in all the cited cases, many cases of sarcoid occur in which the eyes are not affected. Therefore he believes that it is no longer necessary to labor the point that uveoparotid fever and sarcoid are similar diseases and may be different manifestations of the same disease. Sarcoid and uveoparotid fever are closely allied conditions for which the cause is not known, but it will probably be proved that they are due to tuberculosis.

Sulfanilamide Reactions Relieved by Nicotinic Acid.—If the administration of nicotinic acid to patients suffering from pellagra or radiation sickness will ameliorate the symptoms and decrease or eliminate the excretion of abnormal porphyrin, McGinty and his colleagues wondered whether it would have the same desirable effect on patients ingesting sulfanilamide. They have given nicotinic acid to a number of Negro patients receiving large doses of sulfanilamide while they were confined to bed in the hospital. A control urine specimen was obtained before sulfanilamide was administered. During the period of observation, symptoms were carefully noted. On the fourth day of medication, in addition to the sulfanilamide, administration of nicotinic acid was begun in doses of 50 mg. three times a day. Throughout the period of this regimen twenty-four hour specimens of urine were collected and an oxalated specimen of blood was obtained daily. Quantitative determinations of sulfanilamide were made on the blood and urine specimens by the method of

Marshall and Litchfield. Urinary porphyrin was detected by ether extraction of an acidified sample of urine, concentration of the ether extract, acidification with 10 per cent hydrochloric acid and examination with the spectroscope. The response of the patients to the additional administration of nicotinic acid has been most gratifying The unpleasant symptoms and the porphyrinuria were decreased. The most definite clinical change observed was a clearing of mental apathy so often present with the ingestion of sulfanilamide.

Ionization for Hypertensive Epistaxis.—Beck has controlled severe hypertensive epistaxis by ionization in three cases in which ligation of the external carotid was considered The ionization, or iontophoresis, as has been employed for vasomotor rhinitis and hay fever, brought about permanent control of the epistaxis The first was done nearly three years ago and there has been no epistaxis since in any of the patients All three patients have a well marked arteriosclerosis. The thick fibrinous membrane of coagulative necrosis that immediately forms on the surface seems to act as a perfect blanket or cover and seals the leaking vessels. Whatever undesirable changes are produced in the mucous membrane may be considered the lesser of two evils, for control of the bleeding is the immediate necessity. The resulting submucosal fibrosis probably prevents repetitions of the bleeding. In all the cases, packing had been inserted repeatedly in an endeavor to stop the bleeding. In carrying out the procedure the packing which has been placed in the nose to control bleeding is removed a little at a time and to the enlarging nasal surface cocaine and epinephrine solution is applied topically. It is advisable to anesthetize the opposite side of the septum when only one side is involved. The ionizing pack and incorporated electrode are then introduced in the customary manner and the current is applied. A current strength of 10 milliamperes for ten minutes produces a good surface membrane. After-treatment consists of deliberate nonintervention, particularly while the pseudomembrane is present. Sedatives or narcotics are usually necessary from the first twelve to twenty-four hours. After the membrane has come away an attempt at preventing the formation of adhesions which tend to form at places at which the space is very narrow is justified. They do no particular harm.

Cerebrospinal Fluid and Vision.—From his examination of 120 patients who came to the hospital because of failing vision, the diagnosis in forty of whom was acute retrobulbar neuritis, Watkins concludes that the cerebrospinal fluid in acute cases is normal except in those caused by multiple sclerosis. In these, which form from 25 to 50 per cent of the group, the colloidal gold curve may show a strong first zone reaction. In thirty-nine cases of chronic retrobulbar optic neuritis the onset of the visual disturbance was slow and gradually progressive over a period of months rather than weeks. The average age (39) was somewhat higher than in the acute cases (33), with 62 per cent of patients more than 40 years of age. Both eyes were affected slightly more frequently (54 per cent) than one alone and the eyeballs were tender and painful in only 22 per cent Pallor of the optic disks was usually observed (72 per cent), but they were hyperemic in 21 and normal in 7 per cent. The characteristic field was a central scotoma, and the visual impairment showed progression to nearly complete blindness. Lumbar punctures revealed no abnormality in initial pressure, cellular content, total protein or colloidal gold curve. The etiology was unknown in 85 per cent of the cases and proved to be multiple sclerosis in 15 per cent The average age in the thirty cases diagnosed was 52. The course was one of slow progressive loss of vision in the two eyes, although not necessarily equally. The eyeballs were in no case tender and the optic disks were either normal or slightly pale. The diagnosis was made from visual field examinations, the characteristic field being a cecocentral scotoma, although in some cases it was made from a history of overindulgence in alcohol and tobacco and the presence of a central scotoma similar to retrobulbar neuritis, and 40 per cent of these patients improved after reducing or stopping the use of tobacco or alcohol. Cere-

brospinal fluid examinations showed initial pressures which were usually normal. The total protein averaged 33 mg. per hundred cubic centimeters, being distinctly abnormal in only two cases. The colloidal gold curve was negative in all cases. Five patients showed a diminution of vision, papillitis and a constricted field of vision. These five patients were between 4 and 44 years of age. There was tenderness of the eyeball in only one case. There was slight choking of the optic disks and peripheral constriction of the visual fields and some had only unilateral involvement. Lumbar punctures showed normal initial pressures. All cases were of fairly rapid onset, and normal vision was regained. A pansinusitis occurred coincidentally in two cases and hay fever in another. One patient had a definite lead intoxication which seemed of etiologic significance. Of six other patients with optic neuritis, three had transverse spinal cord lesions and retrobulbar neuritis which was thought to be on an unclassified infectious basis but fitted into the clinical syndrome of optical neuromyelitis. The other three had blindness with central scotomas and multiple peripheral neuritis. A necropsy in one of these cases revealed extensive periarteritis. In the three cases of optical neuromyelitis and the two of multiple peripheral neuritis with optic neuritis there was definite abnormality of the cerebrospinal fluid. In the case of periarteritis the fluid was normal. In an additional twenty-two tumor cases and failing vision the author found that the cerebrospinal fluid pressure, cellular content and colloidal gold curve may all frequently be within normal limits but that the total protein is usually increased from two to five times the normal when there is present a central scotoma from the pressure of tumors or aneurysms on the optic nerves or chiasm.

Mottled Enamel in South Dakota.—Dean and his associates state that there are forty-one communities in South Dakota, divided among twenty counties, in which endemic mottled enamel has been demonstrated by survey. In addition there are thirty other places in which mottled enamel is probably endemic. The endemicity is seemingly limited to the smaller communities and rural districts in which the inhabitants obtain their domestic water from the Dakota sandstone, that is, users of artesian water.

Value of Assessing and Prescribing Dosage in Radiation Therapy in Simple Terms. R. Paterson, Manchester, England.—p. 221.

Treatment of Erysipelas with Ultraviolet Energy.—Knapp combines the reports of Titus and Jenkins (who treated eighty-one and fifty cases, respectively) with that of his own (510 cases) on the efficacy of ultraviolet radiation in the treatment of erysipelas. Experience shows that the dosage should be heavy so that the original dose suggested by Ude (twice the erythema dose) has now been increased to from ten to twenty times the erythema dose. A border of 3 or 4 inches of normal skin around the involved area is included in the treatment. If multiple exposures are necessary, the edges are allowed to overlap. If the eyelids are not involved the eyes are covered with black paper or cotton to prevent an ultraviolet conjunctivitis. If the eyelids are involved the patient is instructed to keep his eyes closed during the treatment. Moist packs are prohibited for from twelve to twenty-four hours after the treatment, as they interfere with the proper development of the erythema. Usually no packs are necessary. If the skin feels stiff after the erythema develops, a little petrolatum may be applied to relieve it. If the lesion spreads, the same or an even heavier dose of ultraviolet is given the next day. Most of the patients remark about the relief of pain, which often occurs while the lamp is still being applied. Later there is some increased edema of both the area of erysipelas and the surrounding normal skin. This subsides in from twenty-four to forty-eight hours, and if no further spread or complications occur the temperature drops rapidly to normal, the treated area wrinkles and then desquamates, and in five or six days the entire area is replaced with new skin. In the majority of cases only one treatment is necessary. A comparison of the three series shows that the average number of treatments per case (from 1.3 to 2.06) and the average number of days (from 3.13 to 4.58) from treatment to normal temperature are nearly the same in the three series. The percentage of deaths (7.4) is much greater in the Minneapolis series than in the others (2.4 and 2). It is probable that this can be explained by the fact that Titus and Jenkins' patients were largely private cases, while the author's series was composed entirely of charity patients, many of whom waited until the last moment before allowing themselves to be taken to a hospital. Eighteen of the deaths occurred in cases in which some factor other than erysipelas was the primary cause of death. The greatest value of ultraviolet is shown in the treatment of erysipelas in infants. Erysipelas has always been feared as an extremely fatal disease in small children. Of fifteen children less than 1 year of age treated with ultraviolet radiation, only two died. To this may be added three private cases without a death.

*Presence of Coccidioidal Infection in Phoenix. E. W. Phillips, Phoenix, Ariz.—p. 48.

Coccidioidal Infection in Phoenix.—Phillips has encountered eight typical delayed positive reactions to coccidioidin in the district of Phoenix, Ariz. Two of these positively reacting patients have spent a summer in California within the last two or three years; another lived there for eight years and probably became infected there. Of the eight positive reactors, seven are known to be sensitized to foods, pollens or both. The remaining patient has symptoms and physical signs (including persistent eosinophilia) strongly suggesting the presence of atopic disease but the offending organism has not been found. In three of the allergic patients, prompt relief of symptoms followed the positive reaction. Another, with an excessive local reaction, suffered for three days from malaise, generalized aching and nausea, but no fever. This evidence justifies the suspicion that coccidioidomycosis is present in Phoenix, apparently in a chronic form not previously described. Unless the coccidioidin test is not specific, this organism is a factor in certain cases of asthma and chronic bronchial infection.

Transmission of Syphilis by Blood Transfusion.—McCluskie reports a case of syphilis transmitted by a blood transfusion. The disease did not show itself until two months after transfusion, unless a few reddish macules on the arm were early secondary manifestations—syphilis d'emblée. In both the donor and the recipient the disease responded to relatively small doses of arsenic and bismuth preparations. The Wassermann reactions of the donor and the patient were both tested at the time of the transfusion and were negative, and neither presented any sign of the disease. The donor had jaundice shortly after giving the blood, and the recipient two weeks after transfusion. Two other authentic cases are reviewed from which it is clear that syphilis can be transmitted from donors who are clinically and serologically negative. This fact should be explained to prospective donors, so that, by careful questioning, one may be able to rule out those who have been exposed to infection during the preceding two months. It has been suggested that the greatest safeguard against such accidental transmission of syphilis would be to employ cadaver blood obtained according to the technic of Yudin (1936). Apart from the natural prejudice which the general public in England might have to the practice, it would be possible only when conducted on a large scale with considerable laboratory facilities. It may in the future be practicable to add some innocuous antiseptic—for example, acriflavine—to the blood for a sufficient period before transfusion to ensure sterility. The author has added a small amount of neoarsphenamine (0.45 Gm.) to the transfused blood in emergency cases in which there has been doubt with no untoward effect. These measures were purely empirical, and he has no proof of their efficacy. In addition to the risk to the patient there is the possibility of an action for damages against the doctor who transmits syphilis by transfusion.

*Chemotherapy in Plague Infection. H. Schütze.—p. 266.

Sulfapyridine in Pneumonia.—Anderson and Dowdeswell compare the results in fifty cases of pneumonia treated with sulfapyridine with fifty cases in which nonspecific treatment was given. There were eight deaths in the latter series as compared to one in the series treated with sulfapyridine. The course of the disease was considerably modified by sulfapyridine and the pyrexial period was reduced. The drug appeared to be active against all types of pneumococci.

Chemotherapy in Plague Infection.—Schütze tested the efficacy of a benzylsulfanilamide derivative, sulfapyridine and a diaminodiphenylsulfone glucoside against infection (experimental) with Bacillus pestis in mice and rats. All three compounds produced a definite therapeutic effect; sulfapyridine was more potent than either in both rats and mice. The benzylsulfanilamide derivative protected rats but not mice and the diaminodiphenylsulfone glucoside protected mice but not rats. Antiplague serum injected subcutaneously at the same time as the test dose of Bacillus pestis produced results comparable with those of sulfapyridine. Future experiments may show whether a combination of the two treatments is superior to either alone.

Insulin Resistance and Diagnosis of Thyroid Disease.—Griffiths describes an abnormality of carbohydrate metabolism in thyroid disease which can be detected even in the absence of any significant increase in the basal metabolic rate. This abnormality takes the form of a diminution in the sensitivity of the muscles to insulin. Thus, whereas in the normal subject the rate at which the muscles withdraw sugar from the blood is greatly increased by insulin, this effect is either diminished or abolished in thyrotoxic and in many nonthyrotoxic cases of goiter. The author bases his remarks on the data obtained from a study of thirty-five cases of thyroid disease. In toxic goiter the peripheral insulin response to the insulin-dextrose test is either poor or negligible, denoting an impairment of the power of the muscles to utilize carbohydrate; this is referred to as peripheral insulin resistance. A similar condition of resistance is found in many cases of nontoxic goiter in which, although the basal metabolic rate is not raised, other signs suggestive of thyroid disturbance, such as intermittent tachycardia, increased fatigability, nervousness and the like, are present. In some cases of goiter, both toxic and nontoxic, central resistance to insulin is present. This condition may be described as an enfeeblement of the normal action of insulin in promoting storage of sugar in the liver. With few exceptions, in both types of cases peripheral insulin resistance is considerably diminished by subtotal thyroidectomy. Central resistance is also in general abolished by thyroidectomy, but again it is occasionally unaffected. The possible relationship between peripheral insulin resistance and myasthenia is stressed. In this connection the creatinuria which is a common feature of thyroid disorders is of particular interest, more especially in view of the association of peripheral insulin resistance, creatinuria and myasthenia in other diseases such as diabetes, acromegaly and dermatomyositis. In view of the frequency with which the author has encountered peripheral insulin resistance in cases in which the nonthyrotoxic or psychoneurotic element of goiter enters, he suggests that estimation of this factor might prove to be a valuable method of detecting possible aberrations of thyroid function in patients who, while not thyrotoxic in the sense that they have a raised metabolism, nevertheless complain of weakness, increased fatigability and symptoms of a cardiac or nervous character.

Quincke's Edema Simulating Acute Appendicitis.—Redon reports the clinical history of a man who had severe pains on the right side of the abdomen. His physician observed that the abdomen was supple; moreover, the patient did not vomit; the temperature was 37.5 C. (99.5 F.) and the pulse was 80. The physician recommended the application of ice and decided to wait twelve hours before making a decision. When Redon saw the patient, the general symptoms were still the same. He rejected the diagnosis of appendicitis and in view of the paroxysmic character of the pains he considered the possibility of an acute invagination and decided to resort to a surgical intervention. On opening the peritoneum he was struck by the extraordinary appearance of the ileocecal region. There was a sparkling edematous mass and Quincke's edema was thought of, the more so since there were no other abnormalities; the appendix in particular presented no sign of inflammation, and the ileum and cecum were likewise normal. However, the appendix was removed and the microscopic examination verified that it was free from anatomic abnormalities. The postoperative recovery was uneventful. The patient was discharged from the clinic on the tenth day. Later investigations confirmed the author's first impression. The patient stated that he was subject to frequent urticarial crises, especially after ingestion of fish, and that before the attack in question he had eaten fish and mussels. Thus the case seems to represent a true attack of Quincke's edema or of "visceral urticaria," as Paul Chevallier proposes to designate the condition. The author regards this case as noteworthy because it proves the existence of a visceral form of Quincke's edema, which, although assumed by some, had not been proved as yet. For surgeons, this case explains certain obscure abdominal symptoms and thus diagnostic errors may be avoided.

*Gonadotropic Secretion and Functional Placental Activity: Hormonal Characteristics of Insufficiency, of Normal Condition and of Hyperactivity of Placental Gland. A. Brindeau, H. Hinglais and M. Hinglais.—p. 281.
Question of Parakeratoses, Dermatoses of Sensitization: Is Psoriasis an *Ultravirus Disease?* A. Desaux and H. Prétet.—p. 283.

Gonadotropic Secretion.—Brindeau and his co-workers report studies on the quantitative estimation of the gonadotropic secretion. They used successively two methods of titration: first they employed male mice and later rabbits. The latter method is at the same time convenient, rapid and precise and it constitutes in practice a veritable functional test, a method of measurement of the activity of the placental gland. The activity of the placental gland can be insufficient, normal or exaggerated. The authors take up first the secretion of the gonadotropic hormone in nonpregnant women and demonstrate that in healthy, sexually mature women traces of the gonadotropic hormone are found. However, in certain pathologic conditions, such as amenorrhea, cancer of the cervix uteri and lutein cysts or after the menopause, considerable quantities of gonadotropic hormone may be found. In some of these cases 100 or more rabbit units may be detected per liter of urine. Quantities of about 150 units, the authors regard as uncertain in their diagnostic significance, because they overlap into the zone of those values that indicate a dead ovum. In the table, in which the authors list the quantitative values of gonadotropic secretion during gravidic states, they first mention the amounts that indicate placental insufficiency. In cases of placental insufficiency with certain death of the ovum, up to 500 rabbit units of gonadotropic hormone may be detected, whereas values between 500 and 2,000 units indicate weak placental action but not necessarily death of the ovum. In the presence of normal placental activity between 2,000 and 25,000 units is detected. Values that exceed 25,000 units are indicative of placental hyperactivity. In placental hyperactivity the authors differentiate two groups: 1. Values between 25,000 and 60,000 units are observed in the toxicoses of pregnancy. In hyperemesis gravidarum, for instance, values between 30,000 and 50,000 units have been detected. 2. Values of 60,000 units and higher indicate the presence of hydatidiform mole. The authors show further that gonadotropic titration is an important aid in the early diagnosis of malignant chorionepithelioma. After the evacuation of the hydatidiform mole, the gonadotropic hormone content of the blood should be determined at intervals of about ten days. If the values fall to zero, the woman may be regarded as out of danger. However, if the titer remounts again after temporary decrease, malignant degeneration is certain and operation is necessary.

*Cancer of Lung. Nunes d'Almeida.—p. 221.
Roentgen Therapy in Fibroma of Uterus. *Irene Nunes.*—p. 351.

Cancer of Lung.—Nunes d'Almeida reports sixteen cases of cancer of the lung. The greatest incidence of the disease was between the ages of 50 and 60 years. All patients but one were men. In the majority the disease developed in the right lung. The author found that the symptoms of cancer of the lung are not precise. Early in the development of the disease the patients are in apparently good health. However, they suffer from repeated hemoptysis, frequently from acute pain in the thorax and shoulder of the side in which cancer developed or from dyspnea. All patients report a progressive thinness and cough during which solid material is eliminated. Axillary and cervical metastases may develop in some cases in the absence of symptoms of diseases of the respiratory tract. The diagnosis is made from microscopic study of the material eliminated while coughing or from material taken by biopsy from grown ganglions and confirmed by x-ray examination of the thorax followed by bronchoscopy in the frontal and lateral postures. Pulmonary cancer may be of bronchial or parenchymal (including lobar) type. Bronchial cancer is the most common and acute form in the group. It develops in the wall of the main or large bronchi, partially (or completely) occludes the lumen of the bronchi, rapidly involves the hilar mediastinal and paravertebral ganglions and the lung parenchyma, and gives early metastases. It shows in the roentgenograms by opacities of the atelectatic lobe or lobes of the lung, and during bronchography by the stopping of the progress of the opaque substance at the occluded zones. Sometimes the tumor is not visible, but the stricture of the visible bronchi indicates the presence of cancer in distant bronchi. The parenchymal forms may be either primary, which are benign, or secondary to bronchial cancer, which are acute. Pure parenchymal forms show in the roentgenograms as isolated tumors at either one or various lobes. An early differential diagnosis between bronchial and parenchymal cancer is important because of the fact that parenchymal forms, especially lobar, are amenable to cure by an early operation (lobectomy or pneumonectomy). The earlier the operation and the better the preoperative and postoperative care of the patients, the better the results. Radium locally applied and roentgen treatments are palliative. They are indicated in early bronchial cancer and in advanced parenchymal cancer.

Conservative Surgery in Calculous Cholecystitis. P. Cezar de Andrade. —p. 95.
Cerebral Symptoms in Course of Acute Rheumatic Fever. A. Sampaio Tavares.—p. 97.

Complement Fixation Reaction in Leishmanioses.—Marques da Cunha and Dias state that the complement fixation reaction is not resorted to for the diagnosis of leishmaniosis because there is no proper antigen available for the test. The authors prepared a stable alcoholic antigen from *Leishmania* cultures. They give in detail the technic for the preparation

of the antigen. The authors found that the antigen which they prepared induces (1) strongly positive complement fixation in the blood serum of rabbits which are hyperimmunized with various species of leishmania, (2) positive complement fixation in the blood serum of patients who are suffering from American, visceral and tegumentary leishmaniosis and in animals with experimental leishmaniosis and (3) moderate positive results in the blood serum of patients who have Chagas' disease. A differentiation of the various species of Leishmania which cause the various forms of clinical or experimental leishmaniosis cannot be made by the results of the test.

*Ureteronephrectomy for Renal Tuberculosis. C. van Gelderen.—p. 52.
*Results from Use of Filtered Ultraviolet Rays in Laparotomies. T. Marti, —p. 84.

Ureteronephrectomy for Renal Tuberculosis.—According to van Gelderen there were thirty-nine cases of renal tuberculosis in which ureteronephrectomy was performed at the surgical clinic of the University of Amsterdam between 1919 and 1938. The more extensive operation did not increase either the immediate operative mortality or the mortality of the later course. The ureteral incision healed in almost every instance by primary intention and remained healed. The renal incision presented about the same incidence of wound complications as is seen after a plain nephrectomy. Apparently these complications are not due to the ureter left behind. The removal of the ureter reduces the average duration of wound complications. Empyema of the ureter, cold abscesses and postoperative colics are absent. Even the unfavorable cases do well after ureteronephrectomy. There were three fatalities in this series. The operation presented no disadvantages. The anticipated advantages, however, did not justify themselves completely. The rapid and permanent recovery of the bladder, however, is apparently due to the removal of the ureter. The author recommends this combined operation in all except the early cases of renal tuberculosis.

Filtered Ultraviolet Rays in Laparotomies.—According to Marti, clinical observations on the effect of irradiation with ultraviolet rays in laparotomized patients established the effectiveness of the method in reducing postoperative pain. The therapy, however, was not successful in every case and recourse to analgesics was necessary. Ultraviolet irradiation during the operation had a definite effect in increasing peristalsis during the postoperative period. In various forms of abdominal operations, particularly after an operation for incarcerated hernia, the treatment reduced in some degree the mortality. In cases of diffuse suppurative peritonitis, the results were far from those claimed by Havlicek, who had obtained a 100 per cent cure. The incidence of postoperative thrombosis, embolism and pulmonary complications was reduced. This was particularly striking as far as the occurrence of pulmonary embolism after operation for incarcerated hernia was concerned. The results, however, are far from those claimed by Havlicek. The author feels that the employment of the laparophos lamp in abdominal operations is a valuable therapeutic agent, even though somewhat overrated by its originator.

Genesis and Therapy of Hyperemesis Gravidarum.—Regarding the genesis of hyperemesis gravidarum, Guhr says that the theories about it have undergone many changes but that recent advances in the research on hormones and vitamins have introduced new points of view regarding the pathologic-physiologic processes that are involved in this disorder, and the therapeutic measures that have been based on these new theories have produced considerable success. In order to explain the treatment with vitamin B_1 and a liver extract which is being used successfully at the author's clinic, he reviews the theoretical foundations that correspond to the present insight into the complicated metabolic processes, giving special attention to the hepatic impairment. Following this discussion he reports the results obtained in twelve cases of hyperemesis gravidarum which were treated with vitamin B_1 and a liver preparation. The patients are given intragluteal injections of ampules of liver extract (2.2 cc.) which contain 500 international units of vitamin B_1. At first one ampule of the preparation is injected daily and as soon as improvement is noticeable the injections are given every second day. The total number of injections varies in different cases, but from six to ten are usually sufficient. In especially severe cases more than one injection may be given daily. The diet should be rich in carbohydrates. Discussing the mode of action of the combined administration of vitamin B_1 and liver, the author suggests that it acts as a protective liver therapy, because investigations indicate that a primary hepatic disorder and the involved disturbance in the carbohydrate metabolism are decisive factors in the genesis of hyperemesis gravidarum. Dysfunction of the anterior lobe of the hypophysis is the eliciting cause. Deficiency in vitamin B_1 is not regarded as a causal factor of hyperemesis gravidarum; however, as an adjuvant vitamin B_1 supports the action of the liver extract in that it not only favors an increase in glycogen but also normalizes the disordered carbohydrate metabolism.

Irradiation by Means of Moving Radium Preparations.—Mayer points out that irradiation by means of moving x-ray tubes was suggested as early as 1913 by H. Meyer. In spite of the great importance of this technic, it was neglected until in recent years it was revived in the form of rotation therapy by Dessauer, René du Mesnil de Rochemont and others (see also *Strahlentherapie* **60**:645, 648, abstracted in THE JOURNAL April 2, 1938, p. 1152). In the present report the author describes his own efforts in adapting the moving principle to radium therapy, pointing out that he experimented with moving radium preparations for the first time in 1926 (report in "Nowiny Lekarskie," page 428) and that in 1933 he discussed the therapeutic application of moving radium preparations. He shows that the irradiation with moving radium involves less technical difficulties than does the employment of the moving principle in roentgen therapy. The small and free radium containers can be coupled easily with a driving mechanism consisting of a clockwork or of an electrical device. It is possible to employ various types of movements. The radium container may be moved in straight lines back and forth, or a rotatory or vibratory method may be employed. The author evaluates the mode of action and the distribution of the radium rays, if the moving technic is employed, pointing out that greater uniformity of ray perfusion of the tissues reduces the danger of relapse in case of tumors. Discussing the devices of application, he says that account must be taken of the available radium supply. This applies especially to the radium containers, not so much to the driving mechanism. The author shows in illustrations that the same motor can be used to produce straight-lined back and forth movements, oscillating arc movements or rotating movements. Regarding the determination of the dosage in the treatment with moving radium preparations, the author refers to studies by René du Mesnil de Rochemont on rotatory roentgen therapy.

Measuring of Light Projected Through Coagulating Blood, a Method to Determine Time and Duration of Coagulation. H. Festen.—p. 396.

Circulation in Drumstick Fingers.—De Haas says that many reports about the microscopy of drumstick fingers maintain that there is a strong overfilling of the capillaries. This is of practical significance in that it forms the anatomic basis for the widely accepted opinion that the pathogenesis of drumstick fingers is connected with stasis and cyanosis. However, there are also some investigators who found the capillaries normal or contracted. The author's own investigations aimed at determining possible differences in the brachial circulation of two groups of ten patients with bronchiectasis, in one of which drumstick fingers were present and in the other absent. The studies consisted in capillaroscopy and in the determination of the venous pressure and of the cutaneous temperature. The results of these investigations are recorded in tables. It was found that in drumstick fingers the smallest vessels are not dilated but contracted. The author thinks that this explains some of the peculiarities of drumstick fingers, for instance the localization of this symptom on the extremities that are most exposed to cold, that is, on the fingers rather than on the toes; moreover, the greater incidence in men than in women (in women the capillaries are dilated during menstruation). Regarding the cause of this vasoconstriction the author says that a detailed discussion is impossible in the scope of this article, but he suggests that the vasoconstrictive substances, of which it is known that the organism can produce them, are destroyed in the lungs. In some diseases of the lungs and in congenital heart diseases (among others in bronchiectasis) this filtrating action of the lung fails. The author thinks that it is the impairment, exclusion or overflowing of the pulmonary filter which is of decisive importance for the development of drumstick fingers.

Petrositis. P. G. Gerlings.—p. 504.

Uterine Prolapse in Old Women.—Van Tongeren shows that old women who have a uterine prolapse can often be relieved to a considerable extent by a pessary. Even in case of total prolapse the pessary may be helpful. However, if the treatment with the pessary fails, the operation according to Neugebauer-Le Fort is advisable. After this operation, relapses are less likely than is the case after the operation that has recently been recommended by Kahr. Kahr's operation is even more simple than that of Neugebauer-Le Fort. Kahr too does not counteract the prolapse as such but makes a blockage on the vulva. The author employed Kahr's operation in seven cases but in three of these a relapse resulted. To be sure, all of these women had a total descensus uteri. However, the results obtained with the operation of Neugebauer-Le Fort were more favorable, for of the twenty-five women who were operated on according to this method only three had a relapse and these could now be treated with a pessary, which had not been possible previously. Thus it seems that if relapses do follow the operation of Neugebauer-Le Fort they are usually less serious than those which develop after Kahr's operation.

*Amyloid Deposits in Islands of Langerhans in Diabetes Mellitus. C. van Beek.—p. 646.

Amyloid in Islands of Langerhans in Diabetes.—Van Beek was induced to make histologic studies on the islands of Langerhans of patients with diabetes mellitus by the detection of amyloid deposits in the islands of Langerhans of a woman aged 54 who died in diabetic coma. Reviewing the literature he found reports on hyaline degeneration of the islands of Langerhans in diabetic patients, but he questions that these deposits really are hyaline, for reactions in various staining tests indicate that the substance is amyloid. Studies on the pancreas of fifty-nine patients with diabetes mellitus, whose ages ranged from 5 to 85 years, disclosed amyloid in twenty-five, or 42.3 per cent. In classifying the patients according to age groups it was observed that the amyloid deposits are present only in those over 50 years of age and that with increasing age the incidence of these deposits becomes greater. The author shows that the question whether the amyloid precipitate in the islands of Langerhans is a partial manifestation of a generalized amyloidosis must be answered in the negative. However, the occurrence of occasional amyloid deposits in some pancreatic islands in aged persons, in the absence of clinical signs of diabetes, makes it difficult to decide whether amyloid deposits are the cause or the result of diabetes mellitus. A parallelism with arteriosclerosis, especially of the arterioles, could be demonstrated. The factors leading to the precipitation of amyloid are still unknown.

Vitamin P in Hemorrhagic Nephritis.—Gimsing reports seven cases of hemorrhagic nephritis treated with injections of vitamin P. In no case were there results which could not have been attained as well by rest in bed and diet; in some cases the treatment was without effect, in others it seemed to exert a transitory irritating effect on the kidneys.

*Family with Hereditary Epidermolysis Bullosa. E. D. Bartels.—p. 141.
Skin Transplantation with Film Bandage. M. Olesen.—p. 144.
Eczema Due to "White Ox-Eye" (Chrysanthemum Leucanthemum). P. V. Marcussen.—p. 147.

Hereditary Epidermolysis Bullosa.—Bartels says that in this disorder bullae appear in the parts of the skin exposed to mechanical action, most often on the hands and feet, but also, though rarely in the simple form, on other parts of the body and in the mucous membrane, as in the mouth and throat, and the nails. The content of the blisters is at first clear, later often becoming hemorrhagic. In the simple form the bullae heal completely in from one to two weeks, in the dystrophic form they are followed by more or less marked atrophy of the skin. The disorder as a rule sets in early, often shortly after birth. The prognosis for cure is unfavorable. A tendency to hyperhidrosis is often present; treatment of the hyperhidrosis leads to a not inconsiderable improvement. Of fifty-five members of the family in question twenty-five (eleven men, fourteen women) are known to have epidermolysis bullosa simplex. Transmission seems to be dominant and not connected with the X-chromosome, at least not exclusively. The author believes that ephedrine may be helpful for a definite limited time. The effect of ephedrine apparently supports the theory that there is in these cases a disturbance of the blood vessels or of the nerves and blood vessels.

THE MIND OF MAN AND HIS SECURITY

PRESIDENT'S ADDRESS

ROCK SLEYSTER, M.D.

WAUWATOSA, WIS.

One by one the great plagues that used to devastate mankind are being overcome. No longer does civilized man live in constant fear of cholera, smallpox and bubonic plague. Typhoid has become so rare that many a modern physician has never seen a case of this disease. Even diphtheria is being brought so certainly under man's control that last year twenty-four cities in the United States did not have a single death from diphtheria. Hardly a decade passes without some new announcement of a phenomenal discovery. In our own time we have seen arsphenamine for syphilis, insulin for diabetes, liver for pernicious anemia, biologic preparations for pneumonia and for scarlet fever, sulfanilamide and sulfapyridine for streptococcic and pneumococcic and similar infections. We have seen the rise of physical therapy and the growth of a new field called allergy. We have seen life expectancy rise from 40 years at birth to 62 years. What fields remain to be conquered?

Among the problems which yet confront us, mental defect and mental disease are increasingly significant. They are imposing in their scope. An understanding of the human mind and of human thinking may aid in the solution of problems of government.

On any day nearly 1 per cent of all of the people [1] in this country, actually 1,300,000 people, are incapacitated by epilepsy, by feeblemindedness and by various types of mental illness. The figure is obtained by adding to 550 of every hundred thousand of our population who have nervous and mental disease and who are not in hospitals the total number now being cared for in sanatoriums, hospitals and other institutions. Patients with mental disease occupy 47 per cent of the hospital beds in this country. For the country as a whole, the number of persons hospitalized for mental disease increased more than 40 per cent from 1926 to 1936. The estimated cost of maintenance of these beds is $230,865,000, with an additional cost of $18,178,000 for patients under private care. Three hundred Americans enter institutions for mental patients daily for the first time. In addition to hospitalized patients, several millions are more or less incapacitated because of mental illness or disturbances. In such states as Massachusetts and New York, where hospital facilities are most nearly adequate and where most reliable statistics are available, one out of 150 adults in the present general population is hospitalized because of mental disease. About 1 per cent of the adult population were under care in mental hospitals at some time during the past year. From 5 to 6 per cent of the general population will spend some time in mental hospitals during their lifetime. Including nonhospitalized persons with mental illness, 2 per cent are incapacitated some time of each year. At some time in their lives 10 per cent of the adult general population will be more or less incapacitated by mental illness. Accepting studies made in Massachusetts, fifty-seven of every thousand male infants and fifty-three of every thousand female infants will live to be committed to mental hospitals. It has been estimated that loss of earnings of hospitalized mental patients, plus the cost of maintenance, represents an annual economic loss in this country of $783,586,000. These figures, bluntly stated, define the scope of our problem. Let us see what hope exists in our attack on it.

CHIEF PROBLEMS IN NERVOUS AND MENTAL DISEASE

Epilepsy, or the falling sickness, has been recognized by the historians from Homer to those of today as the most frightening of human illnesses. The sudden loss of consciousness, the convulsions, the shocking accidents and the dependence associated with this condition make it outstanding as a pressing question. Surely intensified and expanded research on epilepsy is most needed. True, there are available in this country a number of research funds and endowments devoted to the study of this disease. We have learned much about the phenomena associated with it. Every new development in the study of the human body, including most recently the electric encephalograph, has been devoted to a study of this condition; yet our progress has been slight. New remedies for diminishing the threshold of excitation, diets and physical methods of treatment which aid in controlling the number of the attacks and which may diminish to some extent their intensity are announced from time to time. Yet there still remains to be found for this disease, as already is available for some other diseases, a method of control or of treatment that can be included in that magic word "cure," which is the inspiration of every true physician. Perhaps it may be found that there is no one epilepsy and that a variety of convulsive disorders concern us. Such a definition of the problem only enhances its importance.

THE SPASTIC CHILD

Again appealing to the physician for as prompt a solution as possible is the question of the spastic child. These children, who from injury at birth or from other

President's address before the American Medical Association at the Ninetieth Annual Session, St. Louis, May 16, 1939.

1. Zubin, Joseph: The Mentally Ill and Mentally Handicapped in Institutions, Pub. Health Rep., supp. 146, 1938, pp. 1-20.

cause develop disability associated with motion of the body and sometimes deterioration of the mental processes as well, command the interest and the pity of all of us. For many of them permanent care in the home or in an institution seems the only answer. The care of these children illustrates how modern medicine, including the knowledge and the work of many specialties, may be brought to bear for prevention and treatment, for reeducation and for complete control. In the prevention of this condition we must study not only the constitution and heredity but all of the toxic changes that may act on the germ cell as it develops within the mother's body. We need the finest control of the art of the obstetrician by whose assistance the child comes into the world. Once the handicap is recognized, the specialist in the care and feeding of children, the orthopedic surgeon, the child psychologist and the psychiatrist must combine in giving their utmost to enable the child to make the most of the functions that it possesses. Perhaps by the very nature of mankind the births of "spastic" children will never be wholly controlled, yet surely the incidence may be reduced to the irreducible minimum and rehabilitation employed to the utmost utilization.

FEEBLEMINDEDNESS

For the control of feeblemindedness, modern medicine must look to the investigators in genetics and heredity for advice in limiting the production of children incapacitated from birth to meet the mental needs of modern civilization. There is no panacea that we can offer for these fundamental problems of humanity and civilization. Certainly it has not yet been established that modern methods of the prevention of conception in their application to mankind as a whole can control the production of such specimens. Neither is there any evidence that laws regulating sterilization of the parents of the feebleminded will in any serious manner diminish the total number of feebleminded. The evidence that is available indicates that at least 10,000,000 people of 130,000,000 in this country bear within their bodies elements which may result occasionally in the production of a feebleminded child. Our nation is not unique in this regard; indeed, some other nations offer a far greater likelihood of increased mental deficiency. Apparently this is one of those problems of mankind in the mass which nature must eventually solve, as nature has settled many another problem of disease in the past. The laws of biology are more immutable than those of man. The fact that even with the best of education and nurture that we can give the feebleminded they still tend to die young and thus do not invariably reproduce is an indication of nature's long range technic in keeping multiplication of the unfit under control.

Let me emphasize again that most authorities are agreed that there has been no continuous increase in the number of the feebleminded, of the mentally defective and of those with mental disease. Such increase as has occurred is the result of the application to these human beings, among all of us, of what modern medicine has done to decrease disease as a whole and thus to prolong life for all of us.

DEMENTIA PARALYTICA

Research in the field of nervous and mental diseases has been particularly concerned in the past ten years with the problem of general paralysis, which the public calls paresis or softening of the brain and which the scientists call dementia paralytica. What great discoveries have led to possible control of general paresis? Foremost was the determination that the spirochetes of syphilis may invade the human brain and there produce this disease. This discovery, made by a Japanese of German training in an American institution, points again to the universality of medical science. Next came the knowledge that drugs used for the control of syphilis, properly applied, may be of great virtue in impeding the progress of this condition. More recently attention has centered on heat treatment or artificial fever produced by various methods. Now here is a disease of which we know the cause and for which we have certain methods of diagnosis and treatment. Are we ready to say that general paralysis can be completely eliminated? Unfortunately no! A great diminution in the total number of cases of syphilis will bring about a lessened number of cases of this disease. Once established in the brain, however, the spirochete seems inevitably to produce damage to the tissues of the nervous system. The most that treatment can do is apparently to stop the progress of such damage. It cannot restore tissue that has been destroyed and degenerated. Until the time comes when every invasion of the spirochete is recognized and controlled at the earliest possible moment, cases of dementia paralytica will continue to demand medical and institutional attention. Complete elimination of this or of any other disease the dissemination of which depends on intercourse between human beings would require a control of the actions and of the lives of men beyond the power of even the most rigid of governments to establish. Such control would involve changes in our methods of living which are inconceivable under any civilization. Men whose minds and wills are animated temporarily by some single motivation as of religion or nation or race, or who follow blindly after strange gods or strange leaders, may sacrifice freedom of thought and freedom of speech and freedom of action to seek a special goal. But eventually the mind awakens and biology triumphs.

DEMENTIA PRAECOX

Dementia praecox, or the so-called insanity of adolescence, now is responsible for at least 60,000 patients in our institutions and perhaps for another 30,000 persons who are in early or in controlled stages of the disease and not yet hospitalized. Indeed, there are some who insist that there may be far more of these people, including noted statesmen, poets and financiers, outside institutions than within. Manifestations of schizophrenia occur frequently in many hundreds of thousands of so-called normal people. The application of the insulin shock method and of the so-called metrazol shock treatment has given a new stimulus and new inspiration to physicians who are responsible for the care of these patients. Apparently these technics bring about fundamental constitutional changes in the bodies of those who are incapacitated. These changes are reflected in the brain. One of the greatest difficulties of the specialist in nervous and mental disease in the past has been the development of technics whereby treatment applied to the human body as a whole could be made effective on the tissue of the brain. Many authorities are convinced that the application of these new methods will enormously reduce the total number of cases of this type in our institutions. Yet every one who stops solemnly and carefully to consider the

knowledge thus far acquired and published would hesitate to evaluate the total progress that can be made. The diseases with which we are here concerned are diseases of a lifetime. Perhaps it may require a lifetime, or several lifetimes, before the physicians of the future will be able to measure in terms that are scientific what has actually been accomplished by these new technics.

EXPANSION OF THE FIELD OF NERVOUS AND MENTAL DISEASES

People in general, and even most physicians, seldom pause to consider the vast expansion that has occurred in the field of nervous and mental disease. New methods of diagnosis, new research in the pathologic changes that occur in the tissues, the science of the psychologist and the art of the psychoanalyst have broadened tremendously the work of the neuropsychiatrist. Most people know about the diseases that have already been mentioned. To the vast majority such terms as myasthenia gravis, apraxia, polioencephalitis, lenticular degeneration, cataplexy, disseminated sclerosis and myelitis represent words with a hazy or slight significance. The modern nomenclature of conditions affecting the nervous system comprises many hundreds of such terms indicating the intricate detail and multiplicity of signs, symptoms and manifestations with which the modern neurologist and psychiatrist must concern himself.

Increasingly the effects of the mind on the physical functions of the body become apparent. The actions of the heart, the stomach and intestines, the blood vessels and the skin may be intimately and seriously affected by mental processes. Yet this does not signify that relations of mind to body may be lumped into a single category or that closing of the mind to physical manifestations will remove them not only from consciousness but also from existence. It means instead that we must intensify our research into the mechanisms that are involved so that the knowing and understanding mind may be truly the master of the body in which it functions.

THE PSYCHIATRIST LOOKS AT THE FUTURE

Most significant among all the aspects of our civilization is not the increase in the number of the mentally afflicted. This, like many another of the problems with which statesmen and economists concern themselves, is a reflection of just one simple fact for which the sciences of medicine and public health must take the responsibility: Human beings tend to survive, to be more healthful, to live longer than they used to. This explains the fact that more people die now from cancer instead of dying from typhoid and from cholera and from smallpox. It explains why spastic children and the feebleminded and the epileptic survive instead of being included in the figures for infant mortality. It explains why heart disease and not tuberculosis is now captain of the men of death. It explains why a people who once troubled themselves little with the problems of old age now find the accumulation of economically dependent men and women past 65 and 70 years of age well nigh their chief concern. Man grown old is not efficient; he cannot labor with his body, and his mind is subject to loss of memory, slowness of action and occasionally queer aberrations.

The problem of the individual who is mentally afflicted is, of course, the concern of the individual psychiatrist much more than it is perhaps the concern of the world as a whole; our world has in these modern days so many concerns which demand its consideration. These concerns arise in most instances not out of individual thinking but out of the psychology of the mass of men, whose opinions are in many instances controlled by stimuli definitely planned to secure a certain result. Perhaps in a day when men were much more accustomed to thinking for themselves and to reasoning from the available knowledge, such influences might not be as effective as they are now. The citizen of the United States in Revolutionary times was a hardy pioneer who had fought the forces of men and of nature successfully and who knew where he wanted to go and what he wanted to do. Today the forces that have been developed by man as a result of modern invention in the field both of materials and of thought are so intricate and so great that frequently they are far beyond the ability of the average man to grasp. Hence bewildered, little men seek constantly for leadership without even sufficient data or background to determine whether or not that leadership is for good or for evil. The breakdown of the sense of individual responsibility is thus a menace not only to the individual but to the nation and to mankind.

Perhaps as a result of the belief of many a man that our civilization has failed, men seek increasingly for security. They wish to be protected against the hazards of unemployment, against the dependence of old age, against the pain and suffering associated with sickness. There has been no lack of self-anointed leaders ready to propose economic and governmental panaceas for meeting the difficulties in the situation. When the Congress of the United States first came to consider social security, the President of the United States warned them against charlatanism in the field of economics. That warning is as important today as it has ever been in the past. It is perhaps more important because of the increased complexity of the situation which confronts us and because of the fact that its long duration has apparently worn away the powers of resistance of many of those who did not at first succumb. But the medical profession, aware of the nature of men and the moral fiber of men, must oppose increasingly those forces which tend to sap vitality, to destroy initiative and to break down individual character. Ethnologists and sociologists know that the life of the race repeats the life of the individual and that the life of the individual repeats the life of the race. They know that nations are but masses of men and that national opinions are the reflections of individual thought. As men become increasingly willing to turn over to their statesmen or to the governments which those statesmen represent the individual responsibilities for which men in the past have fought and died, the vitality of the nation itself must become weakened. The loss of character and of individual initiative may not be pathologic in the sense that mental defect is pathologic. It may not be an illness in the sense that feeblemindedness is a disease, but its effects on the life of the nation as a whole are as weakening as would be a continued increase in the number of mentally defective among us.

These reflections lead to the inevitable conclusion that it is necessary for physicians and for the nation as well to weigh carefully the extent to which the responsibility of the individual for his own care in times of old age and of disease and of unemployment is to be turned over to the nation. In other words, how

great a price are we prepared to pay for what is called security? If national control over illness is to bring about a breakdown in the character of our people so that they will, like many a foreign nation, be ready to yield supinely to the wills of dictators and of dictator nations, the price will have been far too great. If protection against the hazards of illness and of old age is to include an unwillingness to battle against economic forces which bring about unemployment and national destitution, making the individual citizen ready to accept governmental gratuity on every conceivable occasion, again the price to be paid is far more than the goods are worth.

Today the American people stand before the world as a nation of free men where the processes of individual initiative, freedom of thought, controlled research and independent character have placed us in the very forefront of all the peoples in the world in science, in health, in our scale of living, in recreation and in the ability to enjoy life. It is true, as some of our statesmen have said, that not all the people are possessed of all these advantages, yet taken as a whole the statement is true of the vast majority of our people. By the same forces which have brought us to this high place we should be able to overcome the deficiencies of those who have not yet realized these great advantages and to give to them much of that which is enjoyed by the majority. To this purpose the American medical profession has repeatedly dedicated itself. The solutions of the problems of the nations so far as they concern medical care are the responsibility of the medical profession. That is a responsibility which a free medical profession has never avoided and to which it is at this very time giving its most serious consideration. The responsibility for restoring to this nation an economic status in which more and more independent citizens will be able through their own employment and through the returns coming from that employment to supply themselves with the necessities of life is a responsibility which must rest on the leaders of the nation in industry, in finance and in government. With these leaders also American medicine is ready and willing to cooperate in doing all that can be done to spread more widely the benefits of American life and living.

As President of the American Medical Association for the coming year it is to this task primarily that I propose to devote myself.

Lifeless Reports.—The physicians and surgeons of our great teaching hospitals become more and more dependent on technical experts. How easy, as the problems suggest themselves at the bedside, to accept the view that it is fitting that these highly trained and fully equipped men should undertake the investigation. But the result, so often is that from the first the reach is forced into a narrow channel of technicality from which it fails to emerge, and the work ends in one of those reports which, scientific though they may be in their cold logic, unfold no story, and remain uninspiring and lifeless. The fascination and importance of the problem in its wider and practical implications have been concealed, the inspiration that should drive to its solution has been lost, because the problem is no longer seen in its full perspective, a problem primarily concerning the living, in part concerning the dead, and in part deriving from the laboratory. It is just this integration that is of so much consequence to the vitality of medical research; and this integration is, and always must remain, chiefly within the special province of Clinical Science.—Lewis, Sir Thomas: Research in Medicine and Other Addresses, London, H. K. Lewis & Co., Ltd., 1939.

RESECTION OF THE LIVER

CONDITIONS FAVORABLE FOR OPERATION; METHODS; EXPERIMENTAL STUDIES

MARTIN B. TINKER, M.D.
AND
MARTIN B. TINKER JR., M.D.
ITHACA, N. Y.

Relatively few resections of the liver have been reported in surgical literature. Several recent textbooks and at least two modern systems of surgery do not even mention the operation. This is probably because so few cases occur in the individual surgeon's experience, no single surgeon having published reports of more than six cases; yet resections of the liver have been done successfully for many years. In the United States Keen [1] reported his first case forty-seven years ago and added his third case and tabulated seventy-six cases from the world literature forty years ago. Bastianelli,[2] one of the earliest operators, in addition to his original publication forty-three years ago has sent us a personal report of six cases. Garré [3] early stated that "no method can be introduced into general surgery unless it can be executed with simple means which every operator has at hand." More than thirty years ago he reported six successful operations in which hemorrhage was controlled by silk ligature of larger vessels and deep constricting catgut sutures. Growths requiring this procedure may confront any abdominal surgeon at any time and a knowledge of the methods that have been successfully used would make possible the saving of many lives. Fifty-nine instances of resection of the liver have been reported to us in correspondence with members and associates of members of the American Surgical Association and with twenty-four cases previously reported by members of the association it is evident that a large proportion of experienced abdominal surgeons encounter one or more hepatic conditions requiring resection at some time during many years of practice. A discussion of certain phases of this subject was given in an earlier paper.[4] We now repeat important considerations and add a report of experimental studies concerning hemorrhage and shock.

Favorable to safe liver resection are the following facts:

1. The lobes and subdivisions of the liver are supplied by independent arteries, so that one section can be removed without injury to the remaining sections.
2. Anastomoses between blood vessels of different lobes of the liver are free, insuring adequate circulation if a section is cut off from its normal blood supply.
3. Regeneration after removal of liver substance is rapid and quite complete.

The blood supply of the liver has been carefully studied by Martens.[5] His illustrations show that not only do the right and left lobes have each an independent artery but there are branches supplying smaller subdivisions, lobus quadratus and lobus caudatus. His injection and corrosion specimen also showed that if

the artery supplying one lobe was injected the free anastomoses would carry the injection to all parts of the uninjected lobe.

Regeneration was experimentally studied many years ago by Ponfick [6] and also by von Meister.[6] It was found that four fifths of the livers of rabbits, rats and dogs could be removed without fatal outcome and would grow back to approximately normal after such extensive excision. More recently Fishback [7] of the Mayo Clinic has carried out similar experiments with the same results. He found that four-fifths regeneration occurred in from six to eight weeks. These experimental results as regards extent of regeneration were confirmed clinically by Wendel,[8] who found it necessary to do an intestinal resection on a woman whose liver he had resected two years previously.

METHODS OF RESECTION

The most satisfactory exposure of the liver for the average resection is a modified transverse incision slanting slightly toward parallel to the costal border. This is essentially the incision used by Kocher of Bern for surgery of the biliary tract. Study in the dissecting room in Cornell University Medical College, through the courtesy of Drs. Kerr and Papez, showed us that the region under the dome of the diaphragm on the right can be exposed fairly satisfactorily by dividing the eighth, ninth and tenth ribs near the attachment of the costal cartilages. This permits extra upward retraction of from 2 to 4 inches. A vertical extension of the incision upward toward the ensiform cartilage also helps if needed.

The control of hemorrhage has been the problem to which all surgeons have given most attention. McDill [9] suggested compression of the blood vessels and other structures supplying the liver by compression of the hepatoduodenal ligament with a rubber padded clamp applied in the foramen of Winslow. Kirschner [10] also suggests compression by finger pressure or a rubber covered intestinal clamp; but Ravdin, translator and editor of Kirschner's English edition, adds a note to the effect that such a procedure is accompanied by a profound fall in blood pressure and should be used cautiously. Kirschner also mentions that compression should be restricted to the shortest possible time because the intestine cannot recover if the blood supply is shut off more than a quarter of an hour.

Animal experimentation in the physiologic laboratories at Cornell University to determine the effect of compressing the blood vessels, nerves and ducts in the hepatoduodenal ligament has been possible through the cooperation of Prof. Joseph F. Dye. It showed the fall of blood pressure graphically in several cases by tracings on smoked drums. Rapidity and extent of fall in blood pressure varies with each animal, fifteen minutes being apparently about the maximum time that pressure could be safely continued, considerably less in some cases, since the intestine may become alarmingly blue. The clamping might save life in case of violent, uncontrollable hemorrhage; it could be used for a few minutes until other measures could be applied; it seems unnecessary and undesirable as a routine.

Mattress or chain sutures passed with a blunt needle through the entire thickness of the liver before cutting have been found effective in preventing hemorrhage by a large number of surgeons. If a special needle is not available, as is frequently the case, a large probe with an eye may be used or a long needle with the eye end pushed through first. A blunt needle pushes vessels aside, avoiding injury to larger hepatic vessels. It is important that ligatures should not be pulled too tightly, lest they cut through the friable liver tissue if a great thickness is transfixed, requiring heavy tension. To prevent such cutting, catgut sutures through the liver have been tied over celluloid or magnesium plates, rubber tubing or strips of fascia. A mattress needle, small rod or uterine probe as suggested by Dr. Leonard Freeman [11] accomplishes the same result with material which would almost always be available and could be easily removed when it had served its purpose.

Electrosurgery.—Oozing, which is very active from every point of the surface when the liver is cut with a scalpel, was prevented by Keen [1] and others by use of the actual cautery in the days before the introduction of electrosurgery. The radio cutting knife I have found equally efficient for this purpose,[5] more rapid and far less destructive: also radio cutting was found more satisfactory than the spark gap apparatus. Electrosurgical cutting is recommended by Kirschner [10] and has also been successfully used by surgeons of the University of California Clinic, by Lilienthal,[12] by Kelly and Ward,[13] by Howard Gray [14] and by others. Removal of a V shape section in resection of smaller tumors is recommended, when possible, by several surgeons as favoring ready approximation of raw surfaces; this not only helps in controlling hemorrhage but favors smooth healing. Covering the wound in the liver by omentum in animals and man has also been found helpful by Boljarski [15] and others.

Autotransfusion.—Great loss of blood from ruptured cavernous hemangioma or from extensive wounds may give rise to profound and sometimes fatal shock. When these growths or injuries are located, as they are most frequently, near the margin of the liver away from the larger bile ducts, there is little admixture of bile with the blood. In our previous paper autotransfusion of such blood was suggested. The possibility of serious results following autotransfusion from toxic choline derivatives or other substances was suggested by Morton.[16] Kirschner [10] suggests that the blood should be tested to determine the absence of agglutination or hemolysis in cases of rupture occurring more than twenty-four hours previously. He suggests collecting the blood by a ladle or suction; also that it may be citrated and immediately returned into a vein by means of a gauze covered funnel. Our experimental studies at Cornell after autotransfusion of an animal's own blood from hemorrhage of the liver do not show evidence of any serious toxic effect; in fact the tracings on the smoked drums showed either no important change in blood pressure or in some animals a rapid and well maintained rise in blood pressure and improvement in the general condition of the animal. Professor Dye states that he has repeatedly injected acetylcholine into the blood stream of animals experimentally without harmful effects.

Resection has been done for the following conditions:

Benign Growths: Hemangioma, ecchinococcus cysts, gummas, tuberculoma and destructive liver injuries. (Simpler measures are ordinarily available for the last three conditions.)

Malignant Growths: Carcinoma (including adenocarcinoma), sarcoma and hypernephroma.

Cavernous hemangiomas are relatively common tumors of the liver; they are frequently ruptured, giving rise to serious intra-abdominal hemorrhage and, because they are generally thin walled, the bleeding may start spontaneously. Our case, previously reported,[1] belongs in this class of growths. It is important in operating on these patients to excise wide of the growth, as hemorrhage even from a needle prick may be uncontrollable. Packing, actual cautery and even sutures are unavailing unless the stitches are placed in normal liver tissue. This is well shown by the following reports: Gray Turner[17] cites the case of a woman admitted to Guy's Hospital in collapse: a diagnosis of ruptured ectopic pregnancy was made; the abdomen was found to be full of blood; the pelvis was normal; hemorrhage from a hemangioma of the liver could not be controlled by suture or packing; the tumor was removed by cautery and the patient was given an infusion but died after one hour. Severe hemorrhage from a needle prick of a huge angioma of the right lobe is reported by Mantle[18] and quoted by Charles H. Peck.[19] The hemorrhage was uncontrollable by suture or packing and the patient died after two hours. Fatal hemorrhage was also reported by Borst and Chiari[20] and by a number of others. The fairly frequent pedunculated hemangiomas are much less difficult and dangerous. Peck[19] reported such a growth involving the entire left lobe, which was removed after the pedicle was clamped and the stump was closed with a continuous catgut suture; the tumor weighed 3 pounds 14 ounces (1,759 Gm.), the largest tumor removed in this country up to the time of this report. Clar[21] gives details of a successful operation by Schloffer, with a report of thirty others from the literature, an operative mortality slightly over one third of 1 per cent.

Malignant Tumors of the Liver.—As stated in our earlier paper,[4] many surgeons are pessimistic regarding resection of the liver for malignant growths. This has led others to abandon operation, although the experience of Keen,[1] McArthur[22] and Yeomans[23] among Americans and a number of foreign surgeons has shown the possibility of cures up to seven years' duration. Reliable pathologic diagnosis is indispensable. In Keen's[1] case the diagnosis of cylindric cell cancer by Coplin and Tinker was confirmed by William H. Welch and T. M. Prudden; in McArthur's[22] case the pathologic diagnosis of adenocarcinoma by Hektoen and Zeit was confirmed by Fenger; in Yeomans's[23] case the pathologic diagnosis of adenocarcinoma by Jefferies of the Philadelphia Polyclinic was confirmed by Ewing.[24]

Involvement of surrounding organs may offer special difficulties. In McArthur's[22] case the liver was involved by extension from cancer of the stomach, so that resection of the stomach as well as of the liver was required. Wendel[8] operated for carcinoma of the colon associated with cancer of the liver. Kellogg Speed[25] reported extensive involvement of the diaphragm and chest wall requiring resection, together with cancer of the liver. Cullen[26] reported nephrectomy for adenocarcinoma with a malignant condition involving the liver; the patient remained well for four years but eventually died of recurrence in the kidney region, the liver being entirely free from recurrence. All these patients recovered from operation and lived for several years.

Primary carcinomas of the liver sometimes seem favorable for operation because of the infrequency of metastases, slow growth and susceptibility to irradiation, as mentioned by McCallum,[27] Ewing[24] and Sternberg.[28] Adenocarcinomas, which are most frequent, respond well to irradiation. Several growths at first reported to be adenoma have later proved malignant, probably adenocarcinoma. In some cases operation has been repeated; in others postmortem examination or clinical symptoms have left no doubt as to the malignant nature of the growth. Sarcoma has been reported by Elliott[29] and a few others. Ewing[24] believes that there is difficulty in determining the character of the growth in these cases and questions the occurrence of sarcoma, also hypernephroma of the liver.

The unfavorable results following resection for cancer of the liver are based, to a considerable degree, on statistics of operations performed from twenty-five to forty years ago. Moreover Thoele,[30] publishing his report in 1913, overlooked two reports by Keen in 1899 in which the patients were living three years after the operation. Improvement in surgical technic and methods during the past twenty years should favorably influence the results in surgery of hepatic cancer. The combination of irradiation and surgery, which has added such remarkable improvement in the results of treatment of cancer of the thyroid, also a glandular organ, should be of help in similar hepatic conditions.

We have not noticed any report of experimental studies such as are described in this paper. Their important bearing in preventing hemorrhage and in preventing and combating postoperative shock seems to warrant the following summary:

RESULTS OF EXPERIMENTS IN LABORATORIES OF PHYSIOLOGY AT CORNELL UNIVERSITY

1. Clamping the hepatic artery and structures in the hepatoduodenal ligaments showed a gradual but at the end of fifteen minutes an extreme fall in blood pressure. Removal of the clamp is followed by a rapid rise in blood pressure to above normal, which is well maintained.

2. A fall in blood pressure occurs when sympathetic nerves are blocked with procaine hydrochloride and also when sympathetic nerves are stripped from the hepatic artery.

3. Autotransfusion of blood from wounds of the liver gives a prompt and well maintained rise in blood pressure and improvement in the animal's general condition. There is no apparent harmful effect from admixture of bile and other associated products with the blood from extensive lacerated wounds.

THE ANTIBACTERIAL EFFECTS OF THE ORGANIC MERCURIAL COMPOUNDS

WITH SPECIAL REFERENCE TO THEIR USE AS GERMICIDES FOR THE STERILIZATION OF SURGICAL AND DENTAL INSTRUMENTS

JOHN H. BREWER, PH.D.

BALTIMORE

A search of the literature has revealed no carefully controlled work showing that any organic mercurial compound can be relied on to kill the spores of anaerobic bacteria. Nevertheless, claims have been made that these compounds can be depended on for the sterilization of instruments, and vast quantities of them are sold to physicians and dentists for that purpose.

Mercury in its various forms has been used in medicine since the time of the early alchemists, but it remained for Robert Koch [1] to popularize its use as an antiseptic. Immediately after his famous string experiments with anthrax spores the medical world believed that it had in its hands an all powerful germicide which would destroy any disease-producing organism, because apparently Koch had shown that very great dilutions of mercury bichloride would kill the spores of the most resistant organisms. Only a few years after this idea had become thoroughly instilled in the current literature [2] Geppert [3] (1889-1891) with carefully controlled experiments showed that mercury bichloride is a poor germicide although it possesses an almost unbelievable antiseptic or, better, bacteriostatic ability. Mercury bichloride at its best possesses several disadvantages which were known to Koch: It corrodes metal instruments, its apparent killing effect is diminished in the presence of organic matter and it coagulates protein. Furthermore, mercury bichloride cannot be used on the skin over long periods of time without causing dermatitis; it is toxic when injected parenterally and therefore cannot be used in chemotherapy. In spite of these objections and the observations of Geppert and others that mercury bichloride cannot be depended on to kill the spores of anthrax bacilli, it continued to be used because of its great antiseptic action. Chemists throughout the world attempted to produce a mercurial compound which would not have these disadvantages and perhaps might kill the sporulating organisms as well. The first products of these researches possessed few advantages over mercury bichloride, but just at the close of the World War several compounds appeared on the open market in the form of organic mercurials. Some of these were apparently free from the disadvantages of mercury bichloride. With certain types of laboratory tests they seem to be more effective than mercury bichloride. Clinical results indicated that they could be relied on as antiseptics. Many claims were made for them, some rightfully and some without the slightest scientific foundation. Among these claims it was suggested that certain of the products could be used for the "cold sterilization" of surgical and dental instruments. In fact, several manufacturers placed on the market preparations especially designed for this purpose. Practically all the germicidal claims made for such products were based on phenol coefficient tests in which only Staphylococcus aureus and Eberthella typhi were used. No adequate tests were made with sporulating organisms such as Bacillus anthracis, Clostridium tetani or the group of organisms causing gangrene.

Claims for the cold sterilization of instruments and for sporicidal activity found their way into many journals, textbooks and standard references. Even as late as 1937 the Council on Pharmacy and Chemistry of the American Medical Association accepted the claim for one organic mercurial that it is "a potent germicide for the spore-bearing and non-spore-bearing bacteria." [4] No experiments with organic mercurial compounds have been found in the literature comparable to those of Geppert with mercury bichloride.

That sutures cannot be rendered sterile by the use of mercurial compounds was first brought to my attention in 1937 while making a survey of the sterility of catgut sutures for the Council on Pharmacy and Chemistry.[5] Bulloch,[6] Meleney and Chatfield [7] and later Clock [8] pointed out that sutures treated with mercurials are not actually sterile but that the mercurials merely exert a bacteriostatic action on the organisms present. In making this survey for the Council I obtained some sutures which were more than 10 years old. These sutures were "sterilized" by a mercury method and were suspended in 1:1,000 potassium mercuric iodide tubing fluid. When sterility tests were made on them, twelve of the fifty-two sutures were found to contain viable spores, seven of which were of anaerobic bacteria. These results led me to question the advisability of using mercurial compounds for sterilization of instruments, especially after learning that no carefully controlled work had been done in which anaerobic spores were used as the test organism.

DEFINITION OF TERMS DESCRIBING ANTIBACTERIAL ACTION OF THE MERCURIALS

In order to have no misunderstanding regarding the terms used throughout this work, certain words commonly used to describe the antibacterial action of the mercurials are defined.

The present uses of the terms sterile and sterilization are given in a report of the Council on Pharmacy and Chemistry: [9] "The Council on Pharmacy and Chemistry has formally gone on record as disapproving of the use of the terms "sterile," "sterilize" and "sterilization" in a bacteriologic sense other than in their correct scientific significance; i. e., meaning the absence or destruction of all micro-organisms. These terms are not relative and to permit their use in a relative sense not only is incorrect but opens the way to abuse and misunderstanding."

A dissertation submitted to the Board of University Studies of the Johns Hopkins University.

From the Department of Pathology and Bacteriology, Johns Hopkins University, School of *Medicine*.

Dr. J. Howard Brown helped the author in planning this work and gave almost daily guidance and valuable criticism; Dr. Warfield M. Firor gave assistance and suggestions relative to the surgical problems involved, and Drs. Lloyd Felton and Paul N. Leech gave helpful criticism. Miss Elizabeth King gave technical assistance. Various commercial firms supplied the mercurials tested.

The word antiseptic, around which much confusion has arisen in the past, should convey only one meaning: that which is carried in the word itself—the preventing of sepsis or putrefaction.

Regarding the words germicide and germicidal, there has been little difference of opinion among workers. The terms refer to anything that kills germs (microorganisms).

The words bactericide and bactericidal convey the same meaning as germicide, except that they apply to bacteria only.

The word disinfectant is commonly used to refer to substances used on inanimate objects. The meaning, as the word implies, is to render noninfectious. A disinfectant may be either an antiseptic or a germicide; that is, it may either prevent infection by preventing development of the organisms or destroy them outright.

Bacteriostatic or bacteriostasis refers to an agent or state which prevents the development of the organisms. An antiseptic which does not kill may be a bacteriostatic agent.

For a more detailed discussion of the true value of these words one is referred to Patterson's [10] "Meaning of Antiseptic, Disinfectant and Related Words." I am in thorough agreement with him that if one adheres to the strict denotation of these terms there will be no serious confusion among the laity or professional men.

Much confusion in medical literature has arisen because certain fundamental principles have not been taken into consideration. This is especially true concerning mercurial antiseptics or disinfectants. For instance, mercury bichloride, as Abbott [11] has pointed out, is capable, in strong concentration, of killing Staphylococcus aureus, while in very dilute solutions it is only bacteriostatic. Thus a compound may be antiseptic in concentrations too weak to be germicidal. Not only must the concentration of the active agent be considered but the following factors must also be considered in choosing the proper term to describe a particular action: the time of contact, chemical nature of the surrounding medium, the reaction (p_H), temperature, number of organisms present in proportion to the amount of chemical agent, the nature of the organism and the purpose for which the chemical is used.

PRELIMINARY EXPERIMENTS TO SHOW TO WHAT EXTENT ANAEROBES ARE ACTUALLY PRESENT ON INSTRUMENTS AFTER OPERATIONS

As a result of a review of the literature [12] it was decided to determine to what extent anaerobes were actually present on blades after operations. Arrangements were made with the Department of Surgery of the Johns Hopkins Hospital to secure blades used in a series of operations. The nurse in charge of operations had an attendant drop the blades into a sterile tube as the surgeon discarded them. Aseptic precautions were observed and there was very little chance of contamination. The blades from 120 operations were examined and 12 per cent were found to be contaminated with anaerobic spore-forming bacteria. Had these blades been "sterilized" by some inefficient chemical means and reused, there would have been the possibility of infecting other patients. Eight per cent of the contaminated blades were those used for incision of the skin, and this closely parallels the observations of Roberts, Johnson and Bruckner,[13] who found 8.5 per cent of the knives used for making the cutaneous incision to be contaminated with Clostridium welchii. These observations, together with the reports of infections in the literature, seem to indicate that the spore-forming anaerobes should also be used in determining whether a chemical agent is suitable for disinfecting instruments. For the experiments to follow it was decided that pathogenic anaerobes should be chosen on the basis of their mode of attack on the body and the frequency with which they occur in nature. Clostridium tetani, Clostridium septique and Clostridium welchii were chosen. Clostridium tetani remains localized in the tissues and kills entirely by virtue of its toxin. Clostridium welchii and Clostridium septique invade the tissues. Clostridium septique may be found in large numbers in the pericardial and peritoneal cavities after fatal infection, and these infections are always characterized by dark red muscles and edema. In infections caused by Clostridium welchii the muscles are pale and spongy as the result of gas formation. An important characteristic of the clostridia which is not often appreciated is that all the pathogenic members are able to form spores in the animal body (Topley and Wilson,[14] p. 672).

In order to check the technic used and to make the experiments comparable to those of other workers, several different kinds of bacteria have been used as controls. In certain instances Bacillus anthracis (a spore-forming aerobe), Staphylococcus aureus, Corynebacterium diphtheriae, Escherichia coli and Eberthella typhi were used. These include representatives of both the gram-positive and the gram-negative nonsporulating bacteria.

INTRODUCTION TO METHODS USED FOR TESTING THE MERCURIALS FOR THE STERILIZATION OF INSTRUMENTS

The opinion regarding the evaluation of disinfectants is divided into two more or less distinct groups: those who would place every confidence in the results of some laboratory tests and those who accept only clinical data; that is, whether the agent actually works in practice. A far greater number of physicians fall into the latter class and there is much to be said in favor of such an opinion. Garrod (1935) has well stated: *"It is customary to deride laboratory conditions as [being] too far removed from those of practice to afford significant results; the truth is that practical conditions can be imitated closely and in almost every particular. The virtue of a test may in fact be held to depend largely on how far it achieves this, and the whole art of devising it consists in securing the necessary conditions without sacrifice of uniformity."*

If one attempts to evaluate chemical agents for use on the skin or mucous membrane, to act as either antiseptics or disinfectants, many factors at once present themselves which tend to make it impossible to reproduce actual uniform conditions. Among these factors

11. Abbott, A. C.: Corrosive Sublimate as a Disinfectant Against the Staphylococcus Pyogenes Aureus, Bull. Johns Hopkins Hosp. **2**: 50, 1891.

12. At this point, owing to lack of space, a section has been omitted containing a review of the literature concerning theories of the mechanism of killing by the mercurials, previous work on the antibacterial activity of mercurials and methods of testing their bactericidal action for the sterilization of instruments. A short review of the literature relative to the instances of anaerobic infection traceable directly to faulty sterilization of instruments is also included. These sections may be obtained from the author in a special reprint, together with a supplementary bibliography.

tissue permeability, individual variation in the animals, including resistance, drug sensitiveness and many other variants, become apparent if one attempts such tests. In testing these chemical agents for the sterilization of instruments, however, there is no reason why the actual conditions cannot be reproduced to the finest detail. The procedure is an entirely in vitro one with none of the variable elements of in vivo tests entering in. Since this is true there is no reason why the standard method for testing such chemicals should be based on any type of test other than one which exactly reproduces the condition under which the chemical is to be used.

In order to make the proper approach to the problem, it was thought wise to secure some reliable information concerning the actual use of these mercurials in the "cold sterilization" of instruments. Since the larger part of the surgery done by physicians is carried out in hospitals where steam sterilization is accessible, chemical solutions are not used to the extent that they are in the dental field, where very little surgery is done in hospitals. Practically every dental surgeon must provide for the sterilization of his own instruments.

DENTAL QUESTIONNAIRE TO DETERMINE ACTUAL CONDITIONS OF USE OF THE MERCURIALS

Before attempting a study of the antibacterial effects of the organic mercurials used for disinfection of instruments it was necessary to know to what extent these substances were used, the treatment of the instruments before and after attempting sterilization and how long they were left in the solution before being considered safe for use. With the aid of the secretary of the Council on Dental Therapeutics of the American Dental Association, a questionnaire was prepared and sent to all class A and B dental schools in this country and the following dental clinics: Mayo Clinic, Section on Dental Surgery, Rochester, Minn.; University of Chicago, Zeller Foundation Clinic, Chicago; the Forsyth Dental Infirmary for Children, Boston, and the Murray and Leonie Guggenheim Dental Clinic, New York.

In addition, the questionnaire was sent to a representative group of individual dentists over the country, some with very large practices and others with comparatively few patients. Although only sixty-five questionnaires were sent out, the answers represent a cross section of dental practices, since all of the dental schools are included.

Much thought was given to framing the questions in order that they might be clearly understood and so that the answers might be comparable. In view of the definitions given earlier in this paper, some question arose as to the proper word to be used in connection with the treatment of the instruments. Disinfection more adequately describes the actual accomplishment in most cases, but at the time this questionnaire was circulated practically all the commercial solutions carried the phrase "for the sterilization of instruments." A large number of the publications on the subject deal with the chemical sterilization, or chemical agents used for the sterilization, of instruments. Seventy-one per cent of the dentists advocated the use of chemical agents for the sterilization of some instruments. These were usually cutting instruments, scalpels, nerve broaches, tissue shears or instruments made of rubber or other material which would be damaged by boiling.

Sixty-three per cent of those making use of some chemical agent for sterilization use a mercurial. Metaphen, potassium mercuric iodide, merax, mercresin, mercarbolide and merthiolate were the mercurials used. Almost 50 per cent of those using a mercurial used metaphen germicidal solution (1:2,500).

Two of the factors known to influence the chemical disinfection of instruments are the preliminary treatment the instruments receive and the length of time they are allowed to remain in the solution. According to the replies, the time elapsing after the instrument was used until it was placed in the solution ranged from immediately after use to twenty-four hours or until the instrument was needed. The object of this question was to determine whether enough time elapsed for the blood and saliva to dry. In those instances the instruments would be much more difficult to disinfect. Practically all of those suggesting the use of any chemical agent thought it advisable to wash the instruments before placing them in the chemical solution. Several scrubbed with a brush or other scrubbing agent and a few used scrubbing with soap.

There was a great variation in the length of time the instruments were left in the solution, the time varying from one minute to four hours. Almost every minute up to thirty was suggested as the minimum before the instruments were considered safe to use. Sixty per cent of those answering this question considered a period between ten and thirty minutes as the minimum time for sterilization. At the completion of the sterilization 45 per cent suggested drying on a sterile towel and placing in cabinets before use. The other treatments suggested were rinses in various sterile solutions, saline solutions, boric acid, distilled water or alcohol and drying in air.

Regardless of the value of a questionnaire as a means of obtaining reliable information, this one served to furnish the names of the mercurials actually being used, fixed the maximum and minimum time limits and stated the condition of the instruments when placed in the solutions. This information was necessary in designing experiments to simulate actual conditions of use.

MERCURIALS USED IN THE EXPERIMENTAL WORK

The list of mercurials to be used in the experimental work was made up of all those mercurials named in the answers to the dental questionnaire together with those mentioned as agents which might be used as antiseptics or disinfectants in the 1937 edition of New and Nonofficial Remedies. Included are a few new ones which have not been submitted to the Council on Pharmacy and Chemistry or at least have not been accepted at the present date. Some of the mercurials, owing to their dye content or for other reasons, are not suitable for use on instruments and are not promoted for such purposes but have been included because they represent different types of the organic mercurial compounds. Several inorganic compounds have been included to act as controls and some because they are still being employed to a large extent for the disinfection of instruments.

The mercurials used are shown in table 1. The information in this table has been derived from various sources: manufacturers, publications and in some instances consulting chemists. The material will be of value to those unfamiliar with the trade names and to persons wishing to make chemical comparisons.

The chemicals for the most part were secured from the secretary of the Council on Pharmacy and Chem-

istry. In some cases the products were secured directly from the manufacturer and in others they were purchased on the open market.

Since it is not my purpose in this work to compare the efficiency of the various preparations except as to whether they are capable of accomplishing complete sterilization, no attempt has been made to keep the dilutions of the different mercurials constant. The rule generally followed was to use the dilution suggested for the sterilization of instruments or, if the product was not advocated for this purpose, the dilution used was that mentioned for disinfecting the skin or wounds.

In the case of the proprietary mercurials, the solutions were obtained in original packages, since in several instances other chemicals were incorporated to keep the mercurial in solution, to aid in penetration or to prevent rusting of the instruments. In certain instances they are obtainable only in solution form. The nonproprietary chemicals were made up in accordance with suggested directions for use. With some of these it was necessary to make fresh solutions often; with others, large amounts could be made up and kept in glass stoppered bottles in the dark. In every case more than one lot was tested with each organism.

Although it has been shown by Moll,[15] Joachimoglu [16] and others that the reaction (p_H) greatly affects the bactericidal action of the mercurials on spores, no attempt has been made in the experimental work to adjust the p_H. The stock solutions were used as they came from the manufacturer, since it was desired to test the solutions as obtainable by the physician. It was assumed that the solutions on the market would be of the optimal p_H for the maximum killing effect. In the few cases in which I made the solutions, unbuffered distilled water was used. The p_H of the various solutions was found to be between 3.5 and 10.5, and stock solutions of the different mercurials varied little from lot to lot.

EXPERIMENTAL

Method Used to Obtain Spores for the Experimental Work.—Before I began the actual experiments it was necessary for me to have spore suspensions of the various anaerobes in pure culture. One serious source of error in testing disinfectants with spore-forming organisms has been that the method of cultivation before the test has not been conducive to spore formation, with the result that the tests have simply been made on vegetative forms which were no more resistant than staphylococci or other vegetative organisms. An interesting example of this has been found in securing information on the organic mercurials from the manufacturers. A letter was sent to each of the manufacturers of mercurials asking for information on their product, with special regard to its efficiency as an agent for sterilizing instruments. One of the manufacturers in answer wrote a letter including protocols of experiments showing that its particular product was very effective for killing Clostridium welchii. The exact words were " . . . is very effective for the sterilization of instruments. This statement is based on experiments which showed that surgical instruments contaminated with blood and three representative organisms such as Staph. aureus, B. coli and the spore-bearing B. welchii were sterilized in 5 minutes or less."

On close examination of the protocols it was suspected that the organisms had been grown in beef infusion broth containing dextrose in order to get a heavy suspension for the test. Clostridium welchii does not form spores in the presence of this carbohydrate.[14] For confirmation, a culture of the strain used was obtained from the company and cultural tests showed no spores to be formed in the medium as used by the manufacturer. Thus it was necessary before the experiments were attempted to have a method of cultivation for each of the anaerobes used to insure adequate spore formation.[17]

Experiments with Dental Burs.—As a result of the information obtained in the dental questionnaire, the following experiments were made. They follow in every detail the methods used by the physician or dentist in "sterilizing" his instruments. These experiments were made to determine whether or not the mercurials under actual conditions of use were capable of sterilizing the instruments when spores of some of the pathogenic anaerobes were used as the test organism. I do not claim originality for this type of test. Practically every hospital in which infection has occurred and the instruments were suspected has called on its bacteriologic laboratory to make just such tests as these. The one object in this work has been to conduct the tests so that in case the organisms had not been killed they would have had the proper conditions for growth.

For the first series of experiments dental burs [18] were sterilized in a Petri dish in the hot air oven. These burs were removed with aseptic precautions and the serrated cutting edges dipped in defibrinated blood to which had been added spores of one of the test organisms. The burs were then placed upright in holes in a rack made to fit inside a Petri dish. The burs were covered by inverting a Spray dish over them. This whole assembly had previously been sterilized in the hot air oven. The transfer and dipping of the burs were accomplished with the aid of a pair of forceps previously sterilized and flamed between transfers.[19] The contaminated burs then represented the contaminated instruments as they came from a patient's mouth, provided there had been loss of blood and the contaminating organism had been present. The burs in the inverted Spray dish were left at room temperature for varying lengths of time before being placed in the chemical disinfectant. One set was washed immediately (five minutes) after being contaminated and placed in the disinfectant. Sets of burs, that is, one for each organism, were placed in the disinfectant after fifteen minutes, thirty minutes, one hour, four hours and twenty-four hours. This was to determine whether or not it made any difference at what time after use the instruments were placed in the disinfectant. It was thought that the drying of the blood might make mechanical cleansing more difficult and thus affect the sterilization.

Since most of the dentists thought it advisable to wash the instruments and some even to scrub with a brush before placing them in the "germicidal" solution, it was decided to vary this procedure. Some sets of instruments were not rinsed at all, others were rinsed

in sterile tap water and still others were scrubbed until apparently clean with a sterile brush and water.

Although the answers to the questionnaire placed the time for sterilization in the chemical solutions from one minute to four hours, it was decided to use as the minimum time ten minutes. This was the minimum time suggested by some of the manufacturers for the sterilization of instruments. In addition, sets of contaminated burs were allowed to remain in the various solution of potassium mercuric iodide (Parke-Davis germicidal disks). This work was done in 1936, and these were the mercurials which were being or had been used for sterilization of instruments by dentists and dental clinics in Baltimore.

Although this work with dental burs represents seven months of experimental work and sixty complete experiments, a tabulation of the results would be of little value, for in each instance growth was obtained

TABLE 1.—*Mercurials Used in the Experimental Work*

Name	Manufacturer	Chemical Name	Mercury Content	Structural Formula*	Empirical Formula	Type	Comment	pH	Concentration of Type Used
Merthiolate	Eli Lilly & Co	Sodium salt of ethyl mercuri thiosalicylic acid	49%		$C_9H_9O_2S\ Hg\ Na$	$R_1Hg\ S\ R_2$	Where R_1 and R_2 are different organic radicals	9.8	1:1,000 isotonic solution
Metaphen	Abbott Laboratories	Anhydride of 4,nitro-5 hydroxy mercuri ortho cresol	56.57%	sodium salt used 	$C_7H_5O_4Hg\ N$	$R\ Hg\ X$	.	10.5	1:2,500 aqueous germicidal solution
Merphenyl nitrate	The Hamilton Laboratories	Phenyl mercuric nitrate (basic)	63%		C_6H_5HgOH, $C_6H_5HgNO_3$	$R\ Hg\ X$	Where R is an organic and X is an inorganic radical	4.2	1:1,500 boric acid solution
Mercarbolide	The Upjohn Co.	Ortho hydroxy phenyl mercury bichloride	60.95%		$C_6H_5O\ HgCl$	$R\ Hg\ X$		6.5	1:1,000 aqueous solution
Mercresin	The Upjohn Co.	Not a chemical entity		A mixture of mercarbolide and five isomeric amyl ortho cresols		$C_6H_3(CH_3)(OH)(C_5H_{11})$	.	7.4	Tincture (only form available)
Mertonol	McKesson & Robbins, Inc	Acetoxy mercuri 2 ethyl hexyl phenol sulfonic acid	40%		$C_{16}H_{24}O_6S\ Hg$	$R_1Hg\ O\ R_2$	. .	8.5	1:1,000 isotonic solution
Mercuro chrome	Hynson, Westcott & Dunning	Sodium salt of di brom hydroxy mercuri fluorescein	24.26%		$C_{20}H_8O_5Br_2HgNa_2$	$R_1Hg\ X$	. . .	9.1	1:50 aqueous solution
Meroxyl	Hynson, Westcott & Dunning	Sodium salt of 2-4 di hydroxy-3 5 di hydroxy mercury benzo phenone 2′ sulfonic acid	26.29%		$C_{13}H_9O_9Hg_2SNa$	$R_1(HgX)(HgX)$	. . .	7.1	1:200 stabilized aqueous
Mercury oxycyanide	Nonproprietary	. .	85.5%		$Hg(CN)_2\ HgO$	Inorganic	A basic mercuric salt of hydrocyanic acid	9.1	1:6,000 aqueous
Mercuric cyanide	Nonproprietary	. .	83.3%		$Hg(CN)_2$	Inorganic		6.2	1:1,000 aqueous
Potassium mercuric iodide	Nonproprietary	. . .	25.5%	. . .	$K_2Hg\ I_4$	Inorganic	A complex salt formed from 1 mole of HgI_2 and 2 moles of KI	9.2	1:1,000 aqueous
Mercury chloride	Nonproprietary	Mercuric chloride, "corrosive sublimate"	83.3%		$HgCl_2$	Inorganic	.	5.9	1:1,000 aqueous

* The positions of some of the groups are doubtful. For source of information see text

mercurials for periods of thirty minutes, one hour and twenty-four hours. Immediately after being removed from the sterilizing solutions the burs were placed in 40 cc. of 1 per cent sodium thiosulfate for twenty-four hours to neutralize any of the mercurial which might be present, as suggested by Meleney and Chatfield.[7] The burs were removed from this neutralizer, washed in 40 cc. of distilled water and transferred to infusion broth (40 cc.). They were then incubated in an anaerobe jar and removed when growth was noted. In instances in which growth was found, the organisms were identified to make sure that they were the same with which the bur had originally been contaminated.

The mercurials used were merthiolate 1:1,000, metaphen germicidal solution, mercresin and a 1:5,000 even after twenty-four hours' exposure to the disinfectant when the spores of any of the following organisms were used: Clostridium sporogenes, Clostridium septique, Clostridium tetani, Clostridium welchii and Bacillus anthracis.

The technic in these sixty experiments was varied so that some of the experiments simulated every possible combination suggested or actually used by the dentists.

The mixture of the organisms with blood approaches conditions which would be encountered in surgical practice.

Since in dental practice the instruments are not exposed to sodium thiosulfate, it was decided to repeat some of the experiments and omit this treatment.

The burs were rinsed in disilled water after remaining in the mercurials for one hour and for twenty-four hours respectively. They were placed in broth, and growth of the test organisms was obtained in every instance. Mead [20] found metaphen incapable of killing Bacillus anthracis and Bacillus subtilis spores in one hour. He failed, however, to obtain growth after one and one-half hours. His method was to inoculate agar plates from the instruments after rinsing off the excess germicide. He incubated his cultures only forty-eight hours before making readings. Burke, Sprague and Barnes [21] have shown that this incubation period is not sufficient. Meleney and Chatfield [7] have shown that organisms which have been treated with a disinfectant often do not grow out until the fifteenth day, with a maximum number growing out on the thirteenth day.

It is also to be expected that the practice of placing the instrument in the broth would yield a much higher percentage of positive results than that of simply dipping the instruments into melted agar. In actual practice the instruments might be forced into the tissues, and particles in crevices of the instrument would be removed which might not be dislodged by a simple dipping into agar.

EXPERIMENTS WITH DETACHABLE SURGICAL BLADES [22]

Dental burs with deep grooves and serrated edges were chosen because they presented lodging places for bacteria such as would also be found in joints of hinged instruments. This would make mechanical cleansing more difficult and would tax the germicide to a greater extent. The choice of these rough burs gave no idea what the value of such solutions might be in the case of smooth instruments such as scalpels. For this work detachable surgical blades were used. New blades from which the grease had been removed and those from which it had not been removed were used. These blades were used because they could be submerged in the medium and incubated for the duration of the test. The experiments with these instruments were made along with the dental burs, and in no instance were the results different. That is, growth was obtained in every instance. The conditions of testing and the mercurials used were the same as for the dental burs.

Two possible sources of error in this type of test are to be noted. In these experiments the contaminating blood mixture had been made with defibrinated blood. The contaminating mixture should have been made with whole blood, for the bacteria would then have been entangled in the fibrin and might have been more difficult to remove from the instruments. In actual practice the surgeons' blades are affixed in the handle and many crevices are formed which fill with pus, blood and exudate of various kinds, and, if actual conditions were to be approached, the blades should have been affixed to handles. Since positive results were obtained with the smooth blades and defibrinated blood, these factors are minimized; but had the organisms been killed in any instance these would have been very important factors and should be borne in mind in experiments of this type.

After studying the results of the experiments with burs and detachable blades it was realized that, although the experiments reproduced in detail the methods actually employed in chemically "sterilizing" instruments, certain bacteriologic technic was not above criticism for reasons to be described later, and perhaps a true picture of the ability of the mercurial disinfectants had not been obtained. The technic of a group of experiments was outlined so that the action of the mercurials on the spores of several organisms could be tested. These experiments were designed to determine the action of the mercurials not on spores entrapped in blood or dried in films in crevices surrounded by protein but naked spores in a large excess of the mercurial. The greatest attention was paid to bacteriologic technic, so that ideal conditions for killing and no chance of accidental contamination would exist.

DEVELOPMENT OF AN EFFICIENT CENTRIFUGE TECHNIC FOR TESTING MERCURIALS

Are the organic mercurials, under ideal conditions, capable of killing or rendering nonviable the spores of anaerobes? With this question in mind the following experimental work was undertaken. The technic was improved from time to time and these improvements are noted in the text.

Ditthorn and Bartel [23] described what they term a more exact method for evaluating disinfectants. Staphylococcus aureus was the only organism tested by these workers, and although *Chemical Abstracts* in reporting this work makes the statement that the authors used the method for "determining the value of the disinfectant in killing spore suspensions," no mention of any sporulating organism could be found in the original publication.

My first experiments using a centrifuge technic were made before I became familiar with the previously mentioned work of Ditthorn and Bartel, but the method used differed in only a few respects. Cultures of Clostridium sporogenes, Clostridium tetani, Clostridium welchii and Bacillus anthracis were grown on agar by previously described methods which insured spore formation. The spores were washed twice with distilled water, which left only a small sediment of bacteria on the bottom of a 15 cc. centrifuge tube. This washing was done to get rid of any toxin and soluble organic matter that might have been present. The tubes containing the spores were filled to the 15 cc. mark and, by means of a very fine capillary pipet, the organisms were mixed with the disinfectant. Metaphen germicidal solution and merthiolate were the only mercurials used in these preliminary experiments. The mercurial spore suspension was allowed to stand for fifty minutes and centrifuged ten minutes (one hour total). The disinfectant was decanted and the treated organisms were washed twice. The anaerobic organisms were transferred to cooked meat medium under petrolatum by a technic described by Brown [24] for preventing the organisms from becoming covered with petrolatum and thus preventing growth. The spores of Bacillus anthracis that had been treated by this method were streaked out on agar and planted into serum broth as suggested by Süpfle and Degeler [25] in order to insure growth of anthrax spores which had been treated with

disinfectants. All of the cultures in cooked meat and also the serum broth contained viable spores. Since it was possible that the mercurials might have affected the organisms in such a way that although it was possible to recover them in culture mediums they might have no longer been capable of producing disease, guinea pigs were inoculated with 0.5 cc. of the final sediment diluted to 1 cc. at the same time the cooked meat and serum broth were inoculated. Since it was known that the strains of Clostridium welchii and Clostridium sporogenes were nonpathogenic for guinea pigs, these organisms were not used in the animal section of this experiment. One-tenth cc. of 1 : 20 lactic acid was injected along with the tetanus suspension to insure the proper necrosis for infection. The anthrax suspension was injected subcutaneously in the left thigh. The guinea pig inoculated with the untreated anthrax suspension (control) died on the second day; the metaphen and merthiolate treated spores caused death on the third day. The tetanus control and the two animals injected with treated organisms all died on the fourth day after injection.

At this point a critical study of the technic was made and several errors were found. No technic is satisfactory in which there is a possibility that some of the organisms or spores may escape the action of the disinfectant entirely or for even a part of the supposed period of action. In suspension experiments of any type in which the organisms are placed in the disinfectant by means of a pipet, or in the case of the foregoing experiment in which the organisms were already in the centrifuge tube, there are many chances that there will be some bacteria not touched by the chemical agent, or at least not covered by the disinfectant for the full length of the desired period of exposure. This is true even though the suspension is made in one tube and transferred to another tube. Although theoretically possible, I doubt whether one can transfer such a suspension without some of it reaching a point on the tube at which it will not be entirely covered for the duration of the test. The "ringing effect" is also to be considered. That is, the rings left on the test tube as the liquid evaporates may leave a ring of bacteria on the surface of the glass well out of reach of the chemical being tested. This is very important in experiments in which the mercurials are left for as long as twenty-four hours, as in the case of some of the previous tests. This ringing is very noticeable in testing tinctures or solutions containing alcohol such as mercresin. No suspension experiment in which this type of mercurial is being tested can be considered correct unless this ringing factor has been taken into consideration.

To eliminate this source of error, some type of tube which could be sealed off in the flame was sought. If the suspension could be sealed in the proper type of tube and rotated in such a manner that the entire surface would be wetted for the period of exposure to the chemical agent, then this error would have been eliminated. After attempting to seal test tubes off in the flame uniformly, I decided that probably some ampule already on the market might be satisfactory. After trying several types of tubes I found the Judd and Simon [26] modification of the Keidel tube. Tube *A* shown in the accompanying illustration offers several advantages. It has a capacity of 50 cc., which allows a large volume of disinfectant to be used with an insignificant volume of spores. The neck of the tube is already constricted and ready for sealing in the flame. The tube is so constructed that it has a centrifuge bottom and, by cutting the tube off with a hot wire and inserting a sterile cotton plug from a test tube of the same size, one has an ideal centrifuge tube for washing the bacteria. This eliminates another source of error in that it is not necessary to transfer the organisms from the time they are exposed to the disinfectant until they are planted into the medium. The point (bottom) of the tube is not sufficiently small to prevent free flow when the tube is rotated.

Since apparently none of the mercurials tested in the earlier work were capable of killing the spores on short contact, it was necessary to have a machine to rotate the tubes satisfactorily over long periods of time. An off-center cam arrangement was made so that when the tubes were placed on it horizontally they would be entirely wetted in going through each cycle. The dotted lines in *C* show the extremes reached by the meniscus in traveling this cycle. The speed of the motor was set so that eighty complete cycles a minute were made. This was fast enough so that there was no chance for drying in any section of the tube. The tubes were rotated for twenty-three hours. About thirty minutes was required to inoculate from eight to twelve tubes and seal them in the flame before placing them on the machine, and thirty minutes was required for the first centrifuging, so that a total of twenty-four hours elapsed from the time the mercurial came in contact with the spores until it was removed.[27]

A, Keidel tube (50 cc.) as described by Judd and Simon. *B*, tube *A* sealed off properly and ready to be placed on rocking machine. *B'*, improper way of sealing tube; allows collection of air in neck of tube. *C*, tube *B* in horizontal position as placed on rocking machine. Dotted lines show changing positions of meniscus as tube is rocked, demonstrating that the entire tube is wetted during each cycle of the machine. *D*, tube *B* with top removed. Note divided cotton plug.

The spore suspensions of the anaerobes are made to contain approximately 330,000,000 viable spores per cubic centimeter. One cc. of this suspension is placed in the Keidel tube with 40 cc. of the mercurial to be tested and the tube sealed and placed on the rocking machine. After the tubes had been removed from this machine and centrifuged, a filed line was made just above the label, as shown in *B*, and the tubes were opened by removing the top. All the mercurial but about 0.6 cc. can be decanted or pipetted off without disturbing the sediment. The remaining 0.6 cc. is thoroughly mixed with the sediment by means of a pipet, and about 0.2 cc. is removed for animal inoculation. One loop of the spore-mercurial mixture is planted in an appropriate medium and incubated. Forty cc. of

26. Judd, C. C. W., and Simon, C. E.: The Vacuum Tube of Keidel, as Applied to Blood Culture Work, J. A. M. A. 64: 822 (March 6) 1915.

27. The complete technic is available in the special reprint. Its great detail was considered inadvisable for a clinical publication of this work, and it has been condensed here.

sterile distilled water is added and the organisms are resuspended by washing up and down several times with a very fine capillary pipet. The tube is then plugged and centrifuged. This process is repeated three times, making a total of four washings. Although there is practically no turbidity in the final washing, when the sediment is diluted to 0.4 cc. a slight turbidity will remain, indicating the presence of organisms.

The technic in general has been to inoculate the proper recovery medium; that is, a medium which is ideal for the development of the spores if they have not been killed. In addition, mice have been inoculated to see whether or not the spores have been rendered noninfectious if they have not been killed. Representative results are given in table 2 and in most cases the protocols were repeated twice, making three sets of experiments.

The large amount of material in table 2 may appear quite complicated. It is hoped that this short explanation will obviate any difficulties:

As an example, Clostridium septique is considered under mercury bichloride. Spores of Clostridium septique were treated for twenty-four hours with mercury bichloride. The spores still suspended in the mercurial were used as an inoculum and were injected into mice and planted in a culture medium. Column 3 shows that the mice did not die even at the end of fourteen days, indicating that the spores were not capable of producing infection. Column 4 shows that the spores grew out in one day, indicating that the organisms were not killed. The results in column 5 and 6 are the same as those in 3 and 4; the inoculum, however, consisted of spores which had been washed four times to get rid of any mercurial present. The results in column 7 under "inoculum: treated spores in mercurial plus lactic acid" indicate that when the spores were injected along with lactic acid they were capable of producing infection and killing the mice. Column 8 shows that Clostridium septique could be recovered by cultural methods. Columns 9 and 10 show results similar to columns 7 and 8.

COMMENT ON THE CENTRIFUGE EXPERIMENTS

If these mercurials had been bactericidal, it would have been necessary to make many additional tests in order to prove the ability of the organic mercurials to disinfect instruments. Tests in the presence of various body fluids would have been made. Tests for organisms dried in pus, whole blood, saliva, bile or, in fact, any fluid which might be found about the body in operations would have been necessary. These tests would be of little value, since it was shown that the mercurials were unable to kill the spores even in twenty-four hours in the absence of body fluids and other factors which are known to decrease the bactericidal action of the mercurials.

One factor that may have influenced the results of these experiments is the production of sulfides in necrotic tissue. It is well known that sulfides are produced in decomposing tissue. Whether ammonium sulfide or hydrogen sulfide, it would tend to neutralize the mercurials on or about the spores. This will account for certain instances, not recorded in table 2, in which the animals died but no growth was obtained in the corresponding cultural experiments. The sulfide content of perspiration should be considered in experiments with mercurials. A polished coin will turn dark after being handled, owing to the action of sulfide from the skin. This may account for the failure of the mercurials to disinfect the skin in certain tests. Not all these mercurials are affected immediately by sulfides, but as the mercury ionizes the inactive sulfide is formed.

Topley and Wilson [14] (p. 698) state that the washed spores of Clostridium tetani are innocuous. Vaillard and Vincent [28] demonstrated that many millions of spores, when deprived of their toxin, could be introduced intramuscularly into guinea pigs without producing tetanus. Vaillard and Vincent found that if the tissues are injured in any way the spores will develop and tetanus will occur. A 22 gage needle was used for the injection in the present work and the mice usually struggled. This may account for tissue injury and subsequent tetanus infection in each instance with the washed spores. To preclude the possibility that the deaths were caused by the presence of a small quantity of tetanus toxin, as a control experiment some of the washed spores were further washed in an abundance of antitoxin and then in water. These were injected in the same manner as in the test, and death resulted. According to Topley and Wilson [14] (p. 698) tetanus toxin in a dose of 0.0001 cc. will kill a mouse. The design of this test makes it impossible for a toxin content of even 1:1,000,000,000 to be present. If the mercurial treatment is included, the spores were subjected to seven washings and dilution to 40 cc. It has also been shown by Van Ermengem [29] that salts of the heavy metals destroy some anaerobic toxins.

The observations of Moll [15] have been substantiated; that is, some of the mercurials are capable of affecting tetanus spores so that, although not actually killed, they are incapable of causing the death of the animals injected with them. In some instances it would seem that the washing process plays a greater role than the neutralizer in bringing about the recovery of the treated organisms.

Room temperature was used for all the experiments; it varied from 20 to 25 C. No experiments were made to determine the effect of a higher temperature for this is about average room temperature and these agents for "cold sterilization" are usually employed to avoid heating the instruments.

The twenty-four hour treatment period is about as long as could be conveniently employed and is much longer than is customarily used. A chemical agent which would require a longer period would not be practical, for many instruments are expensive and must be sterilized and reused several times in one day.

It is to be reiterated at this point that these experiments were not simply exposure experiments, made according to phenol coefficient methods or the string and bead technic, but were tests in which the organisms were sealed in with the disinfectant and constantly agitated to insure exposure of every organism to the disinfectant for the full period of twenty-four hours. The bacteriologic technic was designed to give accurate information on the one question Are the newer organic mercurials capable of killing the spores of anaerobes under the optimal conditions employed for sterilizing instruments? The answer, evident from a study of the tables, definitely indicates that none of the mercurials tested can be depended on to sterilize instruments in

twenty-four hours even in the absence of organic matter and other factors known to decrease the activity of the mercurials.

SUMMARY

1. A review of the literature shows that claims are made that the various mercurials can be depended on to kill the spore-forming anaerobes.

2. A review of the various methods of testing indicates that in most instances bacteriologic technic has been violated or the tests used were not applicable to spore-forming organisms, so that the results cannot be depended on.

3. In a series of 120 surgical operations, bacteriologic examination of the cutting instruments after use revealed 12 per cent contaminated with spore-forming anaerobes. Eight per cent of the skin knives were found to be contaminated with Clostridium welchii or similar organisms.

4. A study of the mercurial solutions available, summarized in table 1, indicates that these mercurials are used in dilutions of from 1:50 to 1:6,000 and vary in p_H from 3.5 to 10.5. This work was not made for the purpose of comparing the different mercurials available but rather to determine their efficiency as germicides for sterilizing instruments. One cannot help noticing, however, that the commercial products with the highest and lowest p_H were in general the most active.

5. In a series of sixty experiments with dental burs and detachable surgical blades, none of the mercurials were found capable of sterilizing the instruments in twenty-four hours under actual conditions of use. Clostridium welchii, Clostridium tetani and Clostridium sporogenes were used as the test organisms.

6. In preliminary experiments according to the modified methods of Mueller and of Ditthorn and Bartel sources of error were found.

7. An improved centrifuge technic was developed to determine whether the mercurials under optimal conditions are capable of destroying spores of anaerobes. The outstanding features of this technic are as follows: A sealed tube is used in which the organisms are exposed to the chemical agent for twenty-four hours. During this time the mercurial spore mixture is agitated constantly to prevent evaporation "rings" and to insure complete wetting of the entire inner surface of the tube. Settling or layering of the organisms is also prevented. Animal inoculation as well as cultural tests were used to determine the efficiency of the various mercurials with this technic.

8. None of the mercurials were capable of killing the spores of Clostridium tetani or of making them innocuous. The work of Moll was substantiated, for in several instances typical symptoms of tetanus developed in the mice and the mice recovered. Contrary to the common belief, Clostridium tetani could be isolated from the site of injection in all the mice dying from tetanus.

9. In the majority of the cases the mercurials were incapable of killing the spores of Clostridium septique, Clostridium welchii or Bacillus anthracis, even in the

* + indicates not only death of the mouse but also characteristic autopsy results and positive cultures from the animal.

† + indicates not only growth but also identification of the organisms inoculated. The number indicates the day on which growth was first observed.

‡ In these instances the animals developed typical symptoms of tetanus but recovered.

absence of body fluids and under conditions optimal for the action of the chemical agents.

10. Cultural experiments indicate that some of the mercurials may affect the spores in such a way that, although not actually killed, they are no longer capable of producing infection.

11. The results of the cultural tests show that results based on a comparatively short incubation period are not reliable since, in some instances, the treated spores developed only after twenty-four days.

CONCLUSION

1. The conflicting reports in the literature regarding the germicidal efficiency of the mercurials may be explained by noting that the methods of testing, in most cases, are not applicable to spore-forming organisms, in particular those tests which do not differentiate between actual killing and bacteriostatic action.

2. It is to be concluded from the results of the tests described in this paper that none of the mercurials examined can be depended on to sterilize instruments when spore-forming organisms are present. The question of disinfection is quite another problem. In the case of Clostridium tetani none of the mercurials rendered these spores noninfectious after twenty-four hours of contact. The spores were still capable of infecting the mice and producing tetanus. The spores of Clostridium septique and Bacillus anthracis, however, could be rendered noninfectious in certain instances. That is, although it was possible to recover in these cases organisms in cultural experiments, they did not produce an infection when injected into animals.

3. To explain the ability of some of the mercurials to act as antiseptics is beyond the scope of this paper. However, their actual germicidal value for vegetative bacteria is questioned. After it was found that the mercurial solutions as commonly used are incapable of killing the spores of the pathogenic anaerobes in twenty-four hours, it was decided to determine their effect on some vegetative bacteria by the centrifuge method. Just as statements are made that some of these mercurials will kill spore-forming bacteria, some of the manufacturers claim that their particular product will kill vegetative bacteria in ten minutes. One of the mercurials used did not kill Staphylococcus aureus in thirty minutes, although no neutralizers or special recovery methods were used. Other vegetative bacteria were used and the results indicate that some method other than one based on phenol coefficient determination should be used to establish the ability of the mercurials to disinfect instruments.

4. Although it was found that the mercurials as available on the market are not germicidal for the pathogenic anaerobes, it is possible that one of the newer organic solvents, wetting agents or surface tension reductants might affect the spores in such a way that the mercurials would then be able to kill these organisms.

5. The method of testing used in the experimental work is not suggested as a standard method to be used for testing chemical agents for sterilizing instruments but is proposed as a method for determining the action of chemical agents on spores under the most favorable conditions. The object of the method is to eliminate all possible sources of error by insuring the action of the chemical on every spore for the full length of the period of exposure.

RECURRING ATLO-AXIAL DISLOCATION WITH REPEATED INVOLVEMENT OF THE CORD AND RECOVERY

GORDON R. KAMMAN, M.D.
ST. PAUL

Between the atlas and the axis (first and second cervical vertebrae) there are three diarthroses. Two of these are lateral and have to do with articular processes, and the third is mesial. This mesial diarthrosis is between the posterior aspect of the anterior arch of the atlas (first cervical vertebra) and the anterior surface of the odontoid process of the axis (second cervical vertebra). Alinement between the atlas and the axis is maintained by the anterior and posterior atlo-axoid ligaments and by the transverse ligament of the atlas. This transverse ligament of the atlas is one of the most important structures in the body, for on its integrity one's life largely depends. It is attached on each end to a tubercle on the inner side of the lateral mass of the atlas, crosses the ring of this bone, dividing it into a small anterior portion for the odontoid process of the axis and a larger posterior portion for the spinal cord. If either the transverse ligament of the atlas or the odontoid process of the axis (dens) gives way, there is an anterior dislocation of the atlas on the axis. The pyramidal decussation lying just behind the odontoid process may be compressed with resulting paralysis of the extremities.

ATLO-AXIAL DISLOCATION

Dislocation of the atlas on the axis may be one of two types; spontaneous or traumatic.

Spontaneous Dislocation.—According to Watson Jones,[1] this condition is due to hyperemic decalcification of the atlas with loosening of the transverse ligament. This results from infections in the nasopharynx or elsewhere in the vicinity of the base of the skull. All cases have four features in common:

1. They occur most frequently during childhood.
2. They are preceded by inflammation anywhere in the upper cervical region.
3. There is a latent period of from seven to ten days between the time of the infection and the dislocation.
4. The part of the arch of the atlas nearest the infection is decalcified.

According to Woltman and Meyerding,[2] spontaneous atlo-axial dislocation may result in symptoms similar to those of cervical arthritis, pharyngeal abscess, meningitis, encephalitis, bulbar palsy, cerebellar tumor and myasthenia gravis.

Traumatic Dislocation.—Traumatic atlo-axial dislocation is usually due to a fracture of the odontoid process of the axis. This deprives the transverse ligament of the atlas of its anchorage and permits the atlas to slide anteriorly on the axis. The condition results from injuries to the neck, manipulative adjustments, convulsive seizures and birth injuries.

The symptoms of traumatic atlo-axial dislocation may be immediate or delayed. In cases in which the appearance of symptoms is delayed there may be a latent period of days, or even months or years. At the time of the injury the local symptoms may be absent or minimal and may disappear rapidly. Then, after the

2. Woltman, H. W., and Meyerding, H. W.: S. Clin. North America **14**: 581 (June) 1934.

latent period, neurologic signs and symptoms develop. These frequently are obscure and progress very slowly. Cases reported by Schwarz and Wigton [3] show slowly developing symptoms, which usually are more pronounced on one side. In many cases both legs and one arm are involved (as in the case here reported) and the picture is one of a slowly developing spastic paralysis with or without sensory involvement. One patient presented himself with a spastic weakness of the legs. The cause of this was not suspected until several months later, when a roentgenogram of the spine showed a dislocation of the atlas on the axis. Careful interrogation of the patient disclosed the fact that many years previously he had injured his neck in a fall. At the time there were no immediate symptoms.

The reasons given by various authors for the appearance of symptoms after a prolonged latent period are redislocation, progressive dislocation, excessive callous formation, pachymeningitis and pressure myelitis, irritation of the cord due to abnormal motility, late developing osteomyelitis and adhesive arachnoiditis with calcification (arachnoiditis ossificans). Stookey [4] thought that the anchoring effect of the arachnoid on the spinal cord at one point and normal mobility of the rest of the cord produced chronic trauma of the cord with disturbance in cord conduction.

The only case found in the American literature that is similar to the one about to be reported is one described by Elliott and Sachs [5] in 1912:

A man aged 50 fell at the age of 18 and landed on the back of his head. For six months after this he was in bed and was unable to move his head from side to side. He recovered on rest and then served for five years in the army. A few years later he fell, striking his left shoulder, and four or five months after this he showed symptoms of a high transverse myelitis. These disappeared completely on rest. Five years later, following another minor injury, he had temporary paralysis of the legs, accompanied by urinary incontinence. Seven years later he sustained his fourth injury, which resulted in immediate paralysis of the right arm and leg, double incontinence, paresthesia of both legs and weakness of both arms. Roentgenograms showed marked displacement of the atlas on the axis. The patient lived for two years and died of sepsis and other complications. Postmortem examination showed atlo-axial dislocation with involvement of the cord.

REPORT OF CASE

This case, like the one just reviewed, is unusual in that the patient suffered numerous atlo-axial dislocations with consequent symptoms of involvement of the cord, followed each time by complete recovery:

K. R., a white man aged 34, was a periodic drinker to excess of beer. His family, past and medical histories were not relevant to this report. In 1925, while driving a car, he fell asleep and landed in a ditch, sustaining multiple lacerations about the chest, hands, face and head and an injury to the lower part of the back. As he remembers it, he was not able to move his arms or his legs for several days. He was told that he had a sprained back and he remained in bed for three weeks, after which he used crutches for six weeks. Recovery was complete.

About a year later the patient was in another automobile accident and the overturned car came to rest on his neck. His right arm and both legs were paralyzed for several weeks and it was necessary for him to be catheterized for some time after the accident. His neck was taped and he was told that he had torn some ligaments. In about two months he had completely recovered except that since then he has felt a twinge in the back of his neck and down the lower part of the spine every time he stumbles a bit or is jarred in any way.

In 1932 he again rolled over in a car and was unconscious for about fifteen minutes. When he came to he had some pain in the lower part of the back but was not hurt sufficiently to make it necessary for him to go to a hospital. He went to work as a farm hand but quit after two weeks because his back hurt him.

At 2 a. m., Oct. 22, 1936, the patient was admitted to the Ancker Hospital in St. Paul with an admitting room diagnosis of suspected tumor of the cervical cord. The notes are very sketchy, but it is stated that for two years he had been having bladder symptoms (nature not stated). October 21, after he retired a paralysis of the right arm and of both lower extremities developed. Superficial examination at the hospital showed hyperactivity of all tendon reflexes and bilateral ankle clonus but normal plantar responses. There was anesthesia of the right side of the body below the third cervical level and of both sides of the body from about the ninth dorsal segment down. The right arm and both lower extremities were paralyzed. At 5 p. m. October 22 the patient was able to move his left leg and close his right fist, the sensory pattern was the same as it had been on his admission to the hospital. The following day there was some return of motion in the paralyzed extremities. Roentgenograms of the lower part of the spine showed "negative lumbar spine and sacrum. Slight narrowing of the first lumbar vertebra, probably developmental unless due to an old slightly compressed fracture" (see first injury).

June 7, 1937, he was admitted to the Ancker Hospital in an intoxicated condition. He had been in an automobile accident but there had not been any serious injury so he did not remain for examination.

Some time later in June the patient was in another automobile accident and the front of his car was telescoped in such a way as to pin his neck against the back of the driver's seat. He was dazed but not unconscious. For about two days he bled from the mouth but at no time was he paralyzed.

October 12 the patient was feeling well until he stooped over to lock the door of his house before going to work. He felt a stinging sensation in the back of his neck and fell to the floor immediately. Whether or not he was unconscious cannot be determined. Three hours later his wife found him and reported that he could not move his legs or his right arm. He was put to bed and he vomited numerous times. The record shows that on the next day there was a spastic paraplegia with weakness of the right upper extremity. The chart does not indicate that a sensory examination was made at that time. I saw him in consultation October 24 and by that time some of the functions of the right arm had returned. There was sensory impairment below an indefinite level corresponding to about the second lumbar dermatome. The muscles of both lower extremities showed a slight spastic weakness, the tendon jerks were brisk and the plantar responses were not elicited. There was no involvement of the sphincters. Roentgenograms of the cervical spine showed an anterior dislocation of the atlas on the axis with fracture and some displacement of the odontoid process. One week later the right leg was stronger than the left, sensation was normal and both plantar responses had become flexor. A spinal tap was not performed because I wanted to avoid as much as possible all manipulation of the spine. Instead I advised orthopedic consultation and in November a fusion operation was done on the cervical spine by Dr. C. C. Chatterton of St. Paul. Aside from some minor episodes associated with his getting drunk and removing his orthopedic collar from time to time the patient has remained well and has not had a recurrence since the cervical spine became ankylosed.

SUMMARY

1. The transverse ligament of the atlas is one of the most important structures in the body because it maintains the alinement between the atlas and the axis. Dislocation of the atlas on the axis (atlo-axial dislocation) causes compression of the spinal cord with resulting symptoms.

3. Schwarz, G. A., and Wigton, R. S.: Fracture Dislocation in the Region of the Atlas and Axis with Consideration of Delayed Neurological Manifestations and Some Roentgenographic Features, Radiology **28**: 601-607 (May) 1937.

4. Stookey, Byron: Adhesive Spinal Arachnoiditis Simulating Cord Tumor, Tr. Am. Neurol. A., 1926, pp. 129-156; Arch. Neurol. & Psychiat. **17**: 153-178 (Feb.) 1927.

5. Elliott, G. R., and Sachs, Ernest: Observation on Fracture of the Odontoid Process of the Axis with Intermittent Pressure Paralysis, Ann. Surg. **56**: 876-882, 1912.

2. Atlo-axial dislocation may be spontaneous or traumatic.

(*a*) Spontaneous atlo-axial dislocation is due to hyperemic decalcification of the atlas with loosening of its transverse ligament. It follows infections about the nasopharynx and base of the skull.

(*b*) Traumatic atlo-axial dislocation may cause symptoms immediately or after a latent period of varying length.

3. In the case reported here the patient suffered a fracture of the odontoid process (dens) and subsequently had a number of atlo-axial dislocations with resulting symptoms of compression of the cord and recovery.

4. Only one similar case is found reported in the American literature.

VESICULAR PHARYNGITIS AND STOMATITIS

AN UNUSUAL EPIDEMIC OF POSSIBLE HERPETIC ORIGIN

HAROLD D. LEVINE, M.D.
BRISTOL, N. H.
STANLEY O. HOERR, M.D.
AND
JAMES C. ALLANSON, B.S.
BOSTON

During the months of July and August 1938 there was an epidemic of febrile vesicular pharyngitis and stomatitis in three of the summer camps located on the shores of a lake in central New Hampshire. The disease presented three distinctive clinical features: vesicular throat lesions, high infectivity and a benign, self-limited course. Since several consultants as well as ourselves had never encountered this disease, and a survey of the literature did not reveal a report of a similar epidemic, this presentation seems justified despite unavoidably meager laboratory studies. It is to be hoped that the disease may be more completely studied if and when it appears elsewhere.

COURSE OF THE EPIDEMIC

The camps involved in the epidemic will be designated as A, B and C. Camp A is a boys' camp with about 100 campers and thirty-five councilors and attendants. Camp B is a girls' camp and camp C a boys' camp: each accommodates about fifty campers and fifteen councilors and attendants.

In camp A the first cases appeared July 17 and the last case was diagnosed July 31. Although a self-imposed quarantine of the camp was instituted July 19 and all fresh cases were isolated as effectively as camp facilities permitted, the disease eventually developed in sixty-one campers, seven councilors, three Negro cooks and one white cook. The height of the epidemic was reached July 22, with thirteen new cases, and followed a week of almost continuous rainfall.

July 23 a councilor from nearby camp B presented characteristic throat lesions and was promptly isolated, and the camp was unofficially quarantined. Several evenings previously this councilor had visited an eating place frequented by councilors from camp A prior to their quarantine. August 1 three new cases were discovered; five others on August 14 brought the total in camp B to ten, as shown in the accompanying table. By this time the first case had appeared at camp C, at the opposite end of the lake; in the ensuing ten days prior to the close of this camp twenty-one cases in all developed. As in camp A, isolation of cases was ineffectual in checking the epidemic, which had not fully burned itself out by the close of the camp season.

There were 106 cases in the entire epidemic, including three cases outside the camps. So far as is known there were no cases resembling this infection in any of the other three boys' and three girls' camps bordering on the lake. The remaining population of the region consists of 5,000 inhabitants, approximately evenly divided between permanent and summer residents. One of our three outside cases occurred in a youth aged 19 who had had herpes zoster of the right lumbar region about three months previously. The second was in a girl aged 6 years living near camp C, and the third was in a woman aged 33 living near camp A. It is quite possible that there were additional outside cases which did not come to our attention; it is unlikely, however, that many cases in camps A, B and C were overlooked, since campers in whom the disease did not develop had their throats examined daily during the epidemic.

CLINICAL ASPECTS

The disease was characterized by a sudden onset with headache, malaise and a variable degree of sore throat and fever, but the most significant finding (present in all of the cases) was the appearance in the throat of one or more yellowish white, slightly raised vesicles 1 or 2 mm. in diameter, usually surrounded by an intense red areola. These lesions were most frequently found on the faucial pillars (anterior more often than posterior), on tonsillar tissue when present or on the soft palate. Many of the cases seen at camp C (but none in the other two camps) presented, as well, lesions on the buccal mucosa or on the gums near the dentogingival margins, and in one case on the under surface of the tongue. Only one or two lesions might appear in the entire course of the illness, or the entire visible pharynx might be studded with them. The lesions often occurred in small clusters, which later coalesced. In most instances the individual or coalescent vesicles ulcerated, leaving a shallow, punched out, grayish yellow crater measuring from 2 to 4 mm. in diameter; some lesions never ulcerated. The lesions disappeared in from five to ten days, usually outlasting the fever.

In a few of the earlier cases in camp A the mucosa adjacent to the vesicles became deeply injected and even hemorrhagic, with moderate edema, simulating the so-called streptococcic sore throat. In many cases there was swelling of lymphoid tissue in the tonsillar fossa. In a few cases in which the lesions were restricted to the tonsils the appearance resembled a follicular tonsillitis, but pus or caseous material could not be wiped from the tonsillar surface. In several cases marked edema caused the bulging of the fauces usually associated with peritonsillar abscess.

As already indicated, the usual complaints were headache, malaise, feverishness and sore throat. The soreness of the throat was usually not severe, and the symptom was more often brought out only on questioning. Moreover, there was no correlation between the appearance of the throat and the subjective complaints; several of the patients with marked ulceration had no soreness whatever. Dysphagia was rarely met, and no patient complained of hoarseness. The patients with lesions of the mouth as well as of the throat complained of soreness or burning of the mouth, tongue

or gums. In two or three cases the disease was ushered in with severe headache, which disappeared with the onset of fever; in one of these cases the headache lasted several days before fever and throat vesicles appeared.

The highest fever (not exceeding 104 F. in any of our cases) was usually attained on the first day of the illness but occasionally not until the second or third day. The throat lesions usually appeared with the rise in temperature, but occasionally there was no fever until a day or more after the lesions were detected. Conversely, in a few cases early in the epidemic fever preceded the appearance of vesicles by a day or two. The temperature typically remained elevated for from two to four days and then hovered slightly above normal for an additional three or four days. In a few cases the temperature returned promptly to normal after one or two days, only to show slight secondary rises on the fourth or fifth day but never equaling the previous febrile level. Some cases were afebrile throughout.

Physical examinations were consistently negative except for the condition in the throat. No cutaneous eruptions were noted. Rigidity of the neck or the Kernig sign was not elicited in any case. The spleen and liver were not felt nor was there any significant enlargement or abnormal tenderness of the lymph nodes. The ear drums were normal in all cases except two: one showed minimal injection of both drums, rapidly subsiding; the second showed marked injection of one drum, which also subsided rapidly. Atypical systolic cardiac murmurs were heard in three cases; these were said to have been noted before the boys entered camp. The highest pulse rate recorded was 120 beats per minute. In every case throughout the epidemic the lungs remained perfectly clear on physical examination. In two cases, moderate generalized abdominal pain was the initial complaint; abdominal examination, however, was negative and the pain disappeared within twenty-four hours.

EPIDEMIOLOGIC ASPECTS

Although the age incidence varied from 7 to 67 years, the disease appeared to have a predilection for the younger age groups, only fifteen of the 106 cases occurring in persons 18 years of age or over. These are roughly one fourth of the exposed adults, whereas the disease developed in about one half of the exposed campers. The adult members of the camp were probably exposed even more than the campers, since the care of the sick devolved on them. In general, the older the patient the milder was the constitutional reaction.

The maximum incubation period could be established on two patients at camp A. The first was a white youth aged 19, enlisted from the outside to help with the camp cooking; he had no contact with known active cases, but the infection developed five days after he entered camp. The second was a boy aged 10 years who was admitted as a camper (his parents fully aware of the risk) in the first week of the epidemic; the disease developed seven days later.

In view of the alleged relationship between certain herpetic infections and chickenpox, as well as the clinical resemblance of the vesicles to the enanthema of chickenpox, the previous histories of 157 campers were reviewed. The vesicular pharyngitis developed in seventy (or 56 per cent) of 124 campers who had had chickenpox and in eighteen (or 55 per cent) of the thirty-three who had not had chickenpox. Apparently previous infection with chickenpox bears no relationship to this type of pharyngitis

It is noteworthy that during and shortly after this epidemic four cases of herpes zoster auricularis were encountered. Only one of these was in a camper, a boy aged 14 years in camp C who had herpes zoster auricularis beginning August 9 and in whom vesicular pharyngitis developed August 21. Cases occurred in two 16 year old school girls and a third in a woman aged 45. All of the patients bathed in the lake almost daily, but there was no direct contact between any two of them.

Four cases of mild conjunctivitis (so-called pink eye) appeared in camp A and two in camp C. This is regarded as no more than the usual camp incidence. Bacteriologic study of these cases was not undertaken. One patient at camp A had had bronchopneumonia three weeks before the onset of the epidemic, but examination of his lungs gave negative results and he was

asymptomatic at least one week before the disease developed. There were no cases of anterior poliomyelitis or encephalitis in the neighborhood during or following this epidemic.

LABORATORY ASPECTS

Our laboratory studies were necessarily restricted. Leukocyte counts were made in twelve cases during the first three days of the disease and ranged between 5,500 and 11,000 cells per cubic millimeter. Urinalyses carried out in seventy-two cases during the height of the illness and two weeks after the cessation of symptoms were negative in respect to albuminuria, glycosuria and urinary sediment.

The local lesions in fifty-one cases were investigated bacteriologically with direct smears, cultures or both. In fifteen cases smears stained with gentian violet did not show sufficient numbers of spirochetes and fusiform bacilli to be diagnostic of Vincent's infection.[1] Seventeen of twenty cultures carried out in Loeffler's

1. Black, W. C.: Acute Infectious Gingivostomatitis ("Vincent's Stomatitis"), Am. J. Dis. Child. 56: 126 (July) 1938

blood serum, dextrose agar or hormone agar showed a preponderance of gram-positive diplococci surrounded by well marked capsules. In two cases Neufeld typing of these organisms showed capsular swelling with type III pneumococcus antiserum. In addition to the gram-positive diplococci there was the usual mixed growth of gram-positive and gram-negative staphylococci, streptococci and bacilli usually found in the normal mouth. No Klebs-Loeffler bacilli were identified. Direct smears in almost all the remaining cases investigated also showed a heavy preponderance of gram-positive diplococci. Two of the blood cultures made in three febrile cases shortly after the onset were negative, and the third was contaminated.

Cultures of the milk and water in two of the camps were submitted to the state board of health; no significant abnormality was reported.

For the purpose of demonstrating a possible virus etiology, an attempt was made to duplicate the experiments of Youmans,[2] Long [3] and Dodd, Johnston and Buddingh.[4] Material was obtained from the lesions in two cases—in one on the second day of the disease and in the other on the third day—and rubbed well into the scarified cornea of a rabbit. In neither case had a herpetic keratitis developed at the end of forty-eight hours.

COMMENT

The concurrence of four cases of herpes zoster auricularis, a disease rarely encountered in general practice, with these cases of vesicular pharyngitis raises the question of whether one may be an atypical manifestation of the other. The fact that the pharyngeal lesions in most of our cases were bilateral, that they had a predilection for the tonsils and pillars and that the distribution of the pain was local rather than trigeminal is against this possibility.[5] Furthermore, in no patient did a facial paralysis or a cutaneous eruption develop.

The luxuriant growth of encapsulated diplococci and their appearance in large numbers in direct smears from the lesions strongly suggested to us at first that they were etiologically significant. The lesions noted in our cases, however, did not resemble the glistening gray membrane described as typical of pneumococcic pharyngitis (which itself is not a commonly recognized clinical entity).[6] It is also recognized that the pneumococcus may be more easily cultured from the throat in the presence of any acute infection of the upper respiratory tract. Finally, the benign course of this pharyngitis contrasts with the severe consequences of pneumococcic infection as usually observed elsewhere in the body.

The question presents itself whether the buccal lesions in these cases might be the oral manifestation of foot and mouth disease ("aphthous fever" of the French literature).[7] The primary vesicular and secondary ulcerative nature of the lesion is similar in the two. Foot and mouth disease is transmissible from cattle to man.[8] No cases of this disease were reported in cattle in the neighborhood, however, and pasteurized milk was used in all the camps. None of the patients in the series showed lesions of the hand, foot, face or nose, and the rapid spread observed in the present epidemic has not been described in the human form of foot and mouth disease.[9]

Herpetic origin of the disease seems the most likely, although such a conclusion is suggested only by clinical evidence to be outlined later and is therefore open to serious objection. The herpetic nature of some cases of vesicular and ulcerative pharyngitis and stomatitis has been demonstrated.[10] The lesions seen in our cases correspond closely to those described in the literature as typical of herpetic pharyngitis and stomatitis (sometimes called aphthous stomatitis [11] in the English and German literature). The drawing reproduced in Youmans' [2] article, for example, shows lesions on the palate resembling those seen in many of our cases. We were fortunate in having Dr. Perrin Long [3] examine a number of the throat lesions; he has given us permission to quote his opinion that they were herpetic. We do not regard our failure to demonstrate a virus as significant, since the conditions under which the experiments were carried out were far from ideal, and technical difficulties could easily account for it.

Although a search of the literature fails to show a report of an epidemic with purely buccopharyngeal localization of the vesicular lesions, a few epidemics of herpes labialis (occasionally referred to in the older literature as "herpetic fever") have been reported, and in exceptional instances there was involvement as well of the throat, buccal mucosa or gums.[12] Dodd, Johnston and Buddingh [4] recently reported a series of twenty-eight cases of herpetic stomatitis with simultaneous involvement, in a few rare cases, of the soft palate, tonsils and posterior pharynx. The cases appeared in groups, but there were not enough at any one time to warrant the use of the word "epidemic."

SUMMARY

An epidemic of vesicular pharyngitis and stomatitis occurred in three New Hampshire summer camps. The disease, affecting 106 persons, was characterized by a high infectivity and ran a benign, uncomplicated course of four or five days. The chief signs were fever and the appearance of vesicles, which subsequently ulcerated, on the faucial pillars, soft palate and tonsillar tissue when present. The disease occurred in patients from 7 to 67 years of age but had a predilection for the young. The maximum incubation period in two controlled cases was five and seven days. Cultures and direct smears of the lesions showed a preponderance of pneumococci. A herpetic origin of the disease is favored on clinical grounds, although experimental proof is lacking.

THE DISTRIBUTION OF SULFANILAMIDE IN THE EYE

JOHN G. BELLOWS, M.D.
AND
HERMAN CHINN, PH.D.
CHICAGO

The widespread success enjoyed by sulfanilamide and its derivatives in the treatment of some infectious diseases has naturally called attention to possible applications in ophthalmology. Encouraging reports have already appeared in their use in trachoma by Kirk and his associates,[1] Loe[2] and others; in gonorrheal ophthalmia by Magitot and his associates,[3] Luis and Ricardo, Fernandez,[4] Willis[5] and others; in orbital cellulitis by Goldenburg[6] and Szinegh;[7] in abscess of the lid by Szinegh, and in herpetic corneal lesions by Kleefeld.[8] Experimentally, streptococcic infections in rabbits' eyes have been successfully treated with sulfanilamide by Rambo.[9] Little work has been done, however, on the penetration of this compound into the eye, although Marshall and his co-workers[10] demonstrated that it readily entered various tissues and fluids of the body. Rambo, on the basis of a single determination, concluded that it appears in the aqueous and vitreous humors and in the lens after oral administration. The other ocular tissues were not analyzed. The present investigation was undertaken in an attempt to secure information on the distribution of sulfanilamide in the eye under various conditions.

EXPERIMENTAL

1. *Penetration into the Eye After Single Massive Doses by Mouth.*—Sulfanilamide 0.2 Gm. per kilogram of body weight was suspended in approximately 25 to 30 cc. of water and partially dissolved by the addition of several drops of concentrated hydrochloric acid. This solution was then administered by stomach tube to dogs under pentobarbital sodium anesthesia. At specified time intervals, aqueous humor was aspirated and a blood sample drawn. This was followed immediately by the enucleation of the eyeball, which was dissected into the following components: lens, vitreous humor, corneoscleral layer and chorioretinal layer. These were weighed immediately and all tissues but the vitreous humor were transferred to mortars, where they were thoroughly ground with sand and a minimum volume of 15 per cent trichloroacetic acid. Each mixture was transferred quantitatively to a 15 cc. tube and centrifuged for from five to ten minutes. The supernatant liquid was decanted into a test tube calibrated at 10 cc. and the precipitate twice washed with 1 cc. portions of the trichloroacetic acid. The supernatant liquid and washings were combined and diluted to the mark with more of the acid. This solution was diazotized and coupled with dimethyl-alpha-naphthylamine[11] and compared with the properly prepared standards, according to the method of Marshall.[12] The vitreous humor was transferred to a centrifuge tube and deproteinized with 5 cc. of 15 per cent trichloroacetic acid. The remainder of the determination was carried out as already described. To determine the sulfanilamide in the aqueous humor, 7 volumes of water and 2 volumes of 15 per cent trichloroacetic acid were added to each volume of the aqueous. This was centrifuged and aliquot portions of the supernatant liquid were treated as before. Reproducible results could be obtained with as little as from 0.1 to 0.2 cc. of aqueous.

Sulfanilamide was found to penetrate into the eye with great rapidity. Within fifteen minutes after ingestion of the compound, traces could be detected in each of the ocular tissues and fluids. As shown in table 1,

TABLE 1.—*Sulfanilamide (Milligrams per Hundred Cubic Centimeters) in Tissues and Fluids After Large Single Dose (0.2 Gm. per Kilogram)*

	Hours							
	1	2	3	4	6	12	24	48
Blood	2.1	3.3	17.9	18.0	19.1	14.7	4.4	1.1
Aqueous humor	0.7*	1.5	10.1	10.9	11.6	9.2	4.1	0.6
Lens	0.3	0.7	1.8	2.7	8.6	9.5	5.4	2.5
Vitreous humor	0.3	0.7	7.6	8.4	8.6	8.2	5.2	0.4
Corneoscleral layer	1.2	1.8	11.6	13.4	12.3	11.7	3.8	0.7
Chorioretinal layer	2.4	3.3	15.0	15.2	15.0	15.4	4.5	0.7

* The mean of two determinations; all other values are the mean of three or more determinations.

with the exception of the lens all these attain their maximum concentration at about the sixth hour. In the crystalline lens the peak is reached at about the twelfth hour. By far the most rapid rise occurs between the second and the third hour. The ocular constituents and blood showed a five to ten fold increase during this period. Again the lens was the sole exception. Here the sharpest rise was between the fourth and the sixth hour. The concentration of sulfanilamide was found to be in the following order: blood, chorioretinal layer, corneoscleral layer, aqueous humor, crystalline lens and vitreous humor. Those tissues attaining the highest concentration fell the most precipitously. Thus the blood contained 19.1 mg. per hundred cubic centimeters after six hours but only 4.4 mg. per hundred cubic centimeters at the end of twenty-four hours. Similarly the chorioretinal value had fallen from 15 to 4.5 mg. per hundred cubic centimeters in this period and the corneoscleral from 13.4 to 3.8. On the other hand, the lens still contained 5.4 mg. per hundred cubic centimeters after twenty-four hours, although its peak was only 9.5 mg.[12a] The vitreous showed even less of a decrease, dropping only from 8.6 mg. at six hours to 5.2 mg. at twenty-four hours.

Dr. Bellows is research Fellow in Ophthalmology.

12a. This difference in the rate of depletion of sulfanilamide from the crystalline lens as compared to the aqueous and blood may cause an upset in osmotic equilibrium which manifests itself clinically as transient myopia.

After forty-eight hours the lens still possessed 2.5 mg. per hundred cubic centimeters of sulfanilamide—more than three times as much as any other ocular tissue.

2. *Penetration into the Eye After Divided Therapeutic Doses.*—In the previous experiment sulfanilamide was employed in large single doses—doses considerably higher than those recommended for clinical use.[13] The effect of the drug given in therapeutic doses was next investigated.

Sulfanilamide 0.075 Gm. per kilogram of body weight was administered daily in four divided doses. Gelatin capsules containing the required dose was given with the food (forcibly if necessary) at 8 a. m., noon, 6 p. m. and 10 p. m. Blood was drawn and eyes were removed under light ether anesthesia after one, two, four and six days, and the analyses performed as described in the preceding section.

The values thus obtained are summarized in table 2. A fairly uniform level was maintained during the experiment, although the values are far lower than those secured in the previous experiment. Since all analyses were made at 8 a. m. (ten hours after the previous feeding), the values reported represent the minimum concentration during the experiment.

To learn whether the amounts thus determined differed materially from the sulfanilamide concentration at other times during the day, blood was drawn immediately before each administration of the drug. Expressed in milligrams per hundred cubic centimeters, the following values were secured: at noon 2.1, at 6 p. m. 2.7, at 10 p. m. 3.5 and at 8 a. m. 1.4. These values are quite low when one remembers that a blood level of from 5 to 10 mg. per hundred cubic centimeters is advocated for optimum therapeutic action and that such a level can be maintained in man on doses comparable with those used in our experiment.

TABLE 2.—*Sulfanilamide (Milligrams per Hundred Cubic Centimeters) in Tissues After Therapeutic Divided Doses (0.075 Gm. per Kilogram Daily)*

	Dose	Days 1	2	4	6
Blood	0.037 Gm. per Kg. b.i.d.	2.6	2.2	2.7	1.4*
	0.019 Gm. per Kg. q.i.d.	2.1	1.2	3.2	2.3
Aqueous humor	0.037 Gm. per Kg. b.i.d.	1.8	1.5	1.6	1.1*
	0.019 Gm. per Kg. q.i.d.	1.8	1.1	..	2.6
Vitreous humor	0.037 Gm. per Kg. b.i.d.	1.2	1.0	1.6*	1.3*
	0.019 Gm. per Kg. q.i.d.	1.6	1.1	2.2	1.4
Lens	0.037 Gm. per Kg. q.i.d.	3.0	2.8	3.9	2.0†
	0.019 Gm. per Kg. q.i.d.	1.4	2.6	2.8	1.4
Chorioretinal layer	0.037 Gm. per Kg. b.i.d.	2.8	2.1	2.2	2.6*
	0.019 Gm. per Kg. q.i.d.	2.7	2.5	2.2	4.1
Corneoscleral layer	0.037 Gm. per Kg. q.i.d.	1.4*	1.4	4.3	1.4*
	0.019 Gm. per Kg. q.i.d.	1.7	1.7	2.6	2.7

* The mean of two determinations.
† Single determination; all other values are the mean of three or more determinations.

If the same amount of sulfanilamide was given in two doses (at 9 a. m. and 5 p. m.) instead of in four, very little difference was apparent in the tissue content. Table 2 illustrates this close agreement for periods of one, two, four and six days.

3. *Action of Heat and Chemicals on the Concentration in Aqueous Humor.*—In an attempt to increase the concentration of sulfanilamide in the eye on a given dose, the effect of heat and drugs on the eye was investigated. No significant difference in the amount of sulfanilamide could be detected between that found in the aqueous humor of an untreated eye and one to which heat had been applied for two hours. Negative results were also secured with ethylmorphine hydrochloride, atropine and physostigmine. Aqueous humors of eyes that were treated with acetyl-beta-methylcholine chloride (mecholyl), however, showed a distinct increase over the control values, as is evident from table 3.

TABLE 3.—*Effect of Heat, Paracentesis and Drugs on Sulfanilamide in Aqueous Humor*

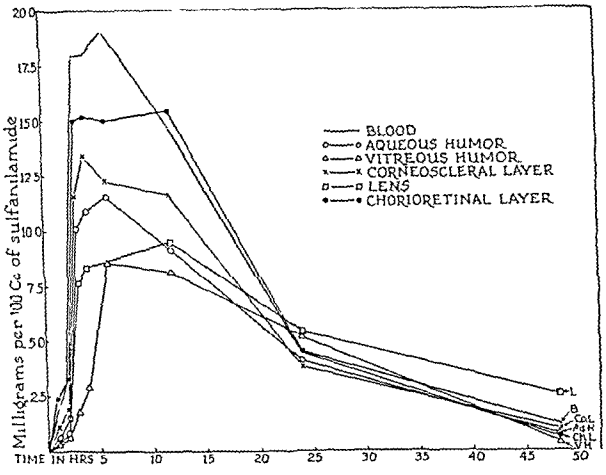
	Time in Hours	Blood	Sulfanilamide, Mg. per 100 Cc. Aqueous Humor: Control Eye	Treated Eye
Heat	2	..	4.0	4.2
Ethylmorphine hydrochloride	2	..	9.5	9.3
Physostigmine	1½	..	3.8	4.0
Atropine	2¼	..	3.4	3.1
Mecholyl	2¼	..	9.2	9.8
Mecholyl	2¼	..	8.0	9.1
Mecholyl	2	..	5.6	8.3
Paracentesis	2½	18.4	8.4	12.7
Paracentesis	2½	22.3	11.4	12.8
Paracentesis	2½	21.1	15.0	17.2

4. *Effect of Paracentesis on Sulfanilamide in Aqueous Humor.*—The aqueous humor of each eye treated with mecholyl was rich in protein. This was evident from the turbidity of the solution, the volume of precipitate after addition of trichloroacetic acid and a marked tendency of the aqueous to clot. Mecholyl, therefore, appears to increase the permeability of the capillaries in the ciliary body, probably through their dilatation. This action is similar to that of paracentesis, which is known to produce a second aqueous whose constituents closely approximate that of blood. The effect of paracentesis on the sulfanilamide content of the aqueous humor was therefore investigated.

Three dogs under pentobarbital sodium anesthesia were given 0.2 Gm. of sulfanilamide per kilogram of body weight by stomach tube. Two hours after administration, the aqueous from the right eye of each animal was aspirated. Thirty minutes later aqueous humor was drawn from each eye and samples of blood were removed for analysis. The analyses, as reported in table 3, indicate that the sulfanilamide content of the second aqueous was increased, lying between the values found for the blood and that for the original aqueous.

5. *Local Applications of Sulfanilamide.*—If sulfanilamide can readily penetrate the conjunctival epithelium and through the cornea, a more effective method of therapy might be attained by local application than by oral administration. To test this possibility, sulfanilamide was dusted on the conjunctival sac and cornea of the animals and allowed to remain for two hours. This produced a moderate reaction, causing chemosis and staining of the corneal epithelium. After repeated irrigation and scraping of the epithelial layers of the conjunctiva and cornea, the underlying subconjunctival tissue and corneal stroma gave a positive test for sulfanilamide. However, one could not rule out contamination entirely. The aqueous and vitreous humors were aspirated by a posterior approach so as to avoid contamination from the conjunctival sac. Not a trace

13. Marshall, E. K., Jr., Emerson, Kendall, Jr., and Cutting, W. C.: Para-Aminobenzenesulfonamide, Absorption Excretion: Method of Determination in Urine and Blood, *J. A. M. A.* **108**: 953 (March 20) 1937.



of sulfanilamide could be detected in either fluid despite the extreme delicacy of the test (sensitive to 1 part in 20,000,000).[13]

When 1 cc. of a saturated solution of sulfanilamide was injected subconjunctivally, a concentration of 0.3 mg. per hundred cubic centimeters was found in the aqueous, a value far lower than that obtained when sulfanilamide is given by mouth.

6. *Sulfanilamide in Tears.*—Tears were collected from two patients receiving 3 Gm. of sulfanilamide daily by mouth. They were analyzed by the method described for aqueous humor. The tears of the first patient, secured three hours after the administration of 1 Gm. of the drug, contained 1.5 mg. per hundred cubic centimeters. Those of the second patient, collected seventeen hours after an equal dose, contained 0.8 mg. per hundred cubic centimeters.

COMMENT

The ready permeability of all tissues thus far examined to sulfanilamide is undoubtedly an important factor in its therapeutic efficacy. The data here presented show that the tissues of the eye can be included

Concentration of sulfanilamide in the ocular tissues and fluids following a single large dose

in this group. The distribution of the sulfanilamide in the various ocular tissues is of interest. The chorioretinal layer possessed the highest concentration of the drug, very closely approximating that found in the blood. This layer is also the most vascular tissue of the eye. Next in order, both of vascularity and of sulfanilamide concentration, is the corneoscleral layer. Unfortunately, the cornea and sclera were not analyzed separately, so the value secured is the mean of an avascular tissue (cornea) and of a slightly vascular tissue (sclera). The aqueous humor possesses the next highest concentration, with the vitreous humor and the lens (an avascular tissue) bringing up the rear. These observations suggest that simple diffusion is the chief mechanism in operation and that the tissues do not act to concentrate the drug. The aqueous and vitreous humors obtain the compound by dialysis from the blood. The lens, having no blood supply, must secure its portion from the surrounding media. This indirect transfer plus the presence of a lenticular capsule results in the slower building up of the peak in the lens and conversely in a slower depletion.

The daily portion of sulfanilamide given in two divided doses maintained practically the same level in the eye as the same quantity administered four times a day. The chart shows that the drop in the various tissues and fluids from the sixth to the twelfth hour is slight; consequently ingestion of the drug every twelve hours should be almost as effective as every six hours. There is no apparent explanation for the difference between the values reported for man and the considerably lower levels obtained by us on dogs.

The action of mecholyl in the eye to produce an increase of the aqueous sulfanilamide may have some clinical significance. However, the increase, though definite, is relatively slight. The results obtained after local administration of sulfanilamide indicate that such procedures are valueless as well as irritating. Since the penetration into the eye of sulfanilamide taken by mouth is so rapid and the levels attained are so high, there is little purpose in administering it by any other route.

Its detection in tears was to be expected, since it has been found in every body fluid thus far analyzed. This is merely another indication of its widespread penetrability.

Since this work was undertaken, sulfapyridine (2- [para-aminobenzene sulfonamido] pyridine) has come into prominence as a possible substitute for sulfanilamide in certain infections. Experiments on this compound similar to those reported here are now under progress in this laboratory.

SUMMARY AND CONCLUSIONS

1. Sulfanilamide can be detected in all ocular tissues and fluids within fifteen minutes after its oral administration.

2. The concentration of sulfanilamide in the eye has been determined one, two, three, four, six, twenty-four and forty-eight hours after a single massive dose by mouth. The maximum is reached around the sixth hour. The concentration of the tissues and fluids examined, listed in decreasing order, were as follows: blood, chorioretinal layer, corneoscleral layer, aqueous humor, lens and vitreous humor.

3. Little difference could be detected in the tissues of dogs when therapeutic quantities were administered twice a day or four times a day.

4. Heat, atropine and physostigmine applied locally have no effect on the sulfanilamide concentration of the aqueous humor. Mecholyl, similarly applied, increases this value.

5. The second aqueous contains somewhat more sulfanilamide than does the original aqueous.

6. Sulfanilamide has been analyzed in tears.

720 North Michigan Avenue.

The Prophecy of Robert Boyle.—The way to our understanding of infectious disease was first clearly indicated by the studies of Pasteur on fermentation. In fulfilment of the prophecy of Robert Boyle made in the seventeenth century that the problem of infectious disease would be solved by him who elucidated the nature of fermentation, the investigations begun by Cagniard-Latour and by Schwann and carried to a brilliant culmination by Pasteur revealed the living and specific nature of the various micro-organisms which cause the several forms of fermentation and especially of putrefaction, and thus led by analogy first to logical speculation, then to experimental proof of the etiological relationship between certain of the minute forms of life and the communicable diseases.—Zinsser, Hans; Enders, John F., and Fothergill, LeRoy D.: Immunity Principles and Application in Medicine and Public Health, New York, Macmillan Company, 1939.

HEREDITARY DEFORMING CHONDRODYSPLASIA

REPORT OF TEN CASES IN ONE FAMILY

CHARLES M. GRANEY, M.D.
BATAVIA, N. Y.

We are all omnibuses in which our ancestors ride, and every now and then one of them sticks his head out and embarrasses us.
—*Oliver Wendell Holmes.*

My purpose in this paper is to report ten cases of such embarrassment; that is, ten cases of a relatively uncommon hereditary disease known as hereditary deforming chondrodysplasia.

Hereditary deforming chondrodysplasia is, as the name implies, a hereditary condition in which abnormal cartilaginous growth results in deformity. Although not all cases show deformities, the name used in this paper has become the accepted designation for this disease and is better and more descriptive than most of the synonymous terms, among which are Ollier's disease, hereditary multiple exostoses, diaphysial aclasis, hereditary multiple enchondromas, multiple cartilaginous exostoses and multiple exostoses.

HISTORY OF LITERATURE

Caesar Hawkins in 1837 is said to have been among the first to describe the condition as "laminated exostoses." However, the report of a typical case occurs in the *Lancet* for July 23, 1825, in the reports from Guy's Hospital.[1] The report discusses a case of Mr. Ashton Key's and the concise description will bear quotation:

> The subject of this affection is a healthy looking lad about sixteen years of age; the bone tumors, which are situated in different bones, first began to form about four years since; their progress has been attended with little or no pain; and it was only on account of their inconvenience that he came into the hospital for relief.
>
> The principal tumour is on the inside of the right tibia, just below the head, and as it were growing from the inner ridge or spine of the bone; the tumour is very firm and immoveable, about the size of an hen's egg, with its surface somewhat irregular; the integuments appear tense, but the tumour is not at all tender upon pressure, and there is no enlargement or irregularity to be detected upon any other part of the bone.
>
> In a similar situation to the preceding tumour, is one upon the opposite tibia, not, however, of such magnitude; upon the lower and outer part of the radius, just above the styloid process, is another bony tumour; and also another immediately above the head of the ulna. As we have before stated, these swellings are not attended with pain, and, from their particular situation, do not interfere much with the action of the muscles; no treatment has yet been had recourse to. The disposition to throw out an exuberance of bony matter is by no means an uncommon occurrence, and is, probably, connected with some peculiar state of the constitution.

The first reports in this country were written by Gibney[2] in 1875-1876 and there are few and scattered reports[3] in the literature until 1915-1917, when Ehrenfried[4] collected and reported all cases in American and foreign literature and wrote the outstanding paper on this disease. Since that time reports have been more numerous, although reports are confused, some authors reporting as hereditary deforming chondrodysplasia cases of Ollier's disease and achondroplasia and others reporting cases without any hereditary history. Two of the best recent papers are by Alley[5] and Mahorner.[6]

The cases here reported correspond in every respect to the syndrome known as hereditary deforming chondrodysplasia, which is defined by Alley as "a hereditary disturbance of bone growth beginning early in childhood and characterized by multiple cartilaginous and osteocartilaginous growths within or on the skeletal system. It is a retardation of normal transformation of cartilage into bone and not primarily a bone tumor."

Clinically patients with this condition may show visible or palpable bumps over the long bones and deformities, particularly in the bowing and shortening of the forearms. Many of them are below normal height, owing to shortening of the long bones. The symptoms that call for treatment are deformity, pressure on nerves or tendons or interference with the motion of joints. Malignant degeneration is said to occur in 5 per cent of cases, but the percentage is probably lower than that.

In diagnosis the hereditary factor, the symmetrical distribution of the exostoses, their multiplicity and the x-ray appearances are important. X-ray examination shows multiple exostosis of the long bones in the epiphysial region but springing from the diaphysial side and directed away from the epiphysis along the line of muscular pull. The exostoses vary from simple spikes to pedunculated and cauliflower types and from well ossified spurs to typical chondromas. The epiphyses may be misshapen or absent, although they do not produce any exostoses themselves.

The bones most frequently affected occur in this order: ulna, fibula, femur, humerus and phalanges. The carpus, tarsus, vertebrae, skull and sternum are not involved, since pure cartilaginous or membranous bone escapes this process.

PATHOLOGY

Microscopically these exostoses show an irregular arrangement of cartilage cells and apparently the cells on the metaphysial side of the epiphysial line are responsible for the growths. A report on case 1 of this series by Dr. Thibaudeau of the New York State Institute for the study of malignant disease reads as follows:

> Sections of tissue received in the case of H. O. C., June 14, 1932, showed a marked hyperplasia of cartilage with, in a few areas, some bone formation. The laying down of bone is irregular but offers no suggestion of malignancy. The cartilage in places shows degeneration with calcium deposits in these areas. In the portions where bone is being laid down, typical histology of growing bone is noted.
>
> Our diagnosis at that time was osteochondroma or chondroma. The histologic picture is not inconsistent with chondodysplasia.

Grossly, the appearance of these growths varies from single bony spurs to chondromas with a slim bony shell. They are not found in embryos or fetuses but cases have been recorded in patients at the age of 2 years, and when the lower end of the ulna is the seat of an exostosis the normal ossification of its epiphysis is

Dr. R. Plato Schwartz, professor of orthopedic surgery, of the Strong Memorial Hospital, Rochester, N. Y., placed at my disposal roentgenograms and records of two of the cases, which came under the observation of his department.

interfered with, indicating that the process is well established before the age of 3. Growth appears to stop when skeletal growth stops at the age of 20 or 22, and regression of the exostoses has been noted in some cases. There is apparently no relation to rickets or syphilis, but the disease is probably related to multiple enchondromas.

INCIDENCE

Ehrenfried in 1915 and 1917 found that the reported cases in the literature total about 700. Of those, ninety-nine cases were reported from the United States. Hale [7] in 1930 collected fifty more cases in the English literature since 1917. The percentage, according to nationality, is 60 per cent German, 27 per cent French, 8 per cent English and 5 per cent all other nationalities. Few Negroes are affected, and in this country Anglo-Americans predominate. The patients comprising this series are of Irish origin. The consensus of statistics shows that males are affected more frequently in the ratio of about 3 to 1. In this series there are eight males and seven females.

Reinicke in 1892 found 172 cases in thirty-six families; one family was followed through five generations; two families were followed through four generations, fifteen through three generations and twelve through two generations.

Ehrenfried in 1917 showed heredity as a factor in 176 of 234 cases, 174 occurring in forty-two families: in two through four generations, in fifteen through three and in twenty-one through two. In the family here reported there are fifteen cases in three generations. It is transmitted by males more frequently than by females · by fathers thirty-five and by mothers twenty times, according to Ehrenfried. Two mothers had affected children by different husbands and one father had affected children by two marriages. In two cases it was transmitted by unaffected mothers and in two instances it was seen to skip a generation. In this series it was transmitted by the mother in three instances and by the father twice. It is said that no cases have been reported of the condition being transmitted by an unaffected male, but there appears to be no reason why this should not be true.

Keith [8] believes the inheritance to be mendelian in character, but Oberndorf claims that there is no definite sequence to it.

ETIOLOGY

The etiology of this condition is obscure, and many theories of etiology and mechanism of its production have been advanced. The neoplastic theory is not tenable, as growth and development of exostoses stop at the age of 20 to 22 years with the attainment of skeletal maturity. It is apparently unrelated to rickets or vitamin deficiency; if it were, there should be no hereditary factor.

Kelly Hale,[7] in an attempt to test the question of infectious origin, fed blood and saliva from his patients to fifty pairs of white mice without the production of tumors in any of their progeny. It is unrelated to syphilis or tuberculosis. Kahn tests were done on three of this series and all gave negative results.

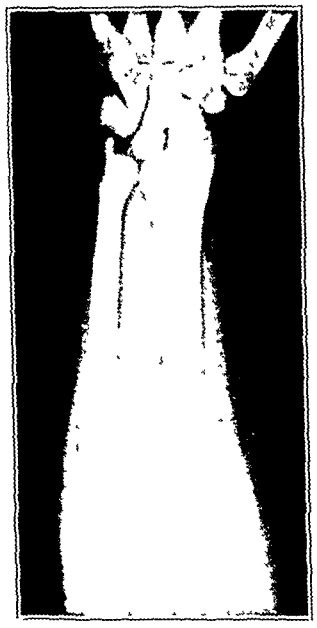

Fig. 1 (case 1).—Left forearm, showing pedunculated type of exostosis

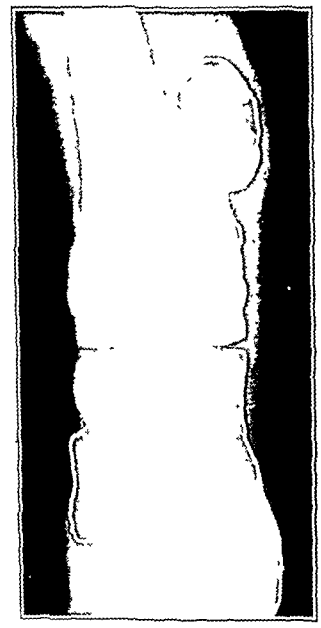

Fig. 2 (case 3).—Right knee, showing chondromatous type of exostoses of femur and tibia.

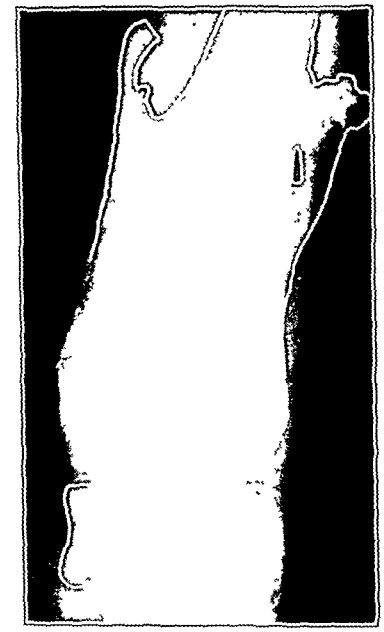

Fig. 3 (case 3).—Left knee, showing exostoses of femur and tibia.

The distribution of the disease is the same as that of thyroid deficiency, and the possibility of a glandular disturbance, as of the thyroid or pituitary, has been considered by some.

Keith and Janssen think that it is due to the failure of the process of breaking down of bone and shaping or modeling of the bone, as described by John Hunter.

Hale, working on the basis that the bones most frequently involved are those which are most frequently fractured and that the incidence is highest in those countries in which skeletal trauma is greatest, has advanced the interesting theory that it is produced by impressions made on the germ plasm, consequent to fractured bones and their complex healing process or that the patients "are made susceptible through transmission from past generations of various obnoxious environmental experiences."

7. Hale, Kelly: Ann. Surg. 91: 92 (July) 1930.

8. Keith, A.: J. Anat. 54: 101, 1919-1920.

Geschickter and Copeland[9] believe that a failure in adequate development of the periosteum results in (1) a failure of the cortex to attain full thickness and (2) the failure of an inadequate periosteum to limit the growth of bone.

Hume[10] believes that it is due to the abnormal behavior of the cells of the growth disk and a failure of subperiosteal bone to keep pace. He states that an abnormal stimulus to the center of the disk and failure of ossification results in enchondroma. Abnormal stimulus to a localized portion of the periphery of the disk results in single pedunculated exostoses and a more generalized stimulus of the growth disks of the long bone results in multiple exostoses. None of these theories are completely satisfying and it would be surprising if they were, as the question of the cause and method of production of this condition involves the highly complex and fundamental problems of heredity and of bony growth.

cases deformities are present. Seven of the cases were proved by x-ray evidence. Three others presented exostoses on examination. Four of the patients are dead, two of whom had been examined by Dr. Cole and Dr. Knoll and were known clinically to have had exostoses. The other patients are said by the family to have had definite exostoses. The other living patient I have not had an opportunity to examine because he lives at a distance.

REPORT OF CASES

CASE 1.—Miss H. O'C., aged 27, a nurse, was admitted to St. Jerome Hospital, April 7, 1931, for the excision of bony spurs from the right radius and ulna because of pain and interference with movements of the wrist. Unfortunately roentgenograms are not available. No pathologic examination was made on the excised specimens. The operative result was good.

June 14, 1932, the patient was again operated on, this time for pain in the left upper quadrant of the abdomen, and a tumor was excised from the ninth left rib. The operative result was good.

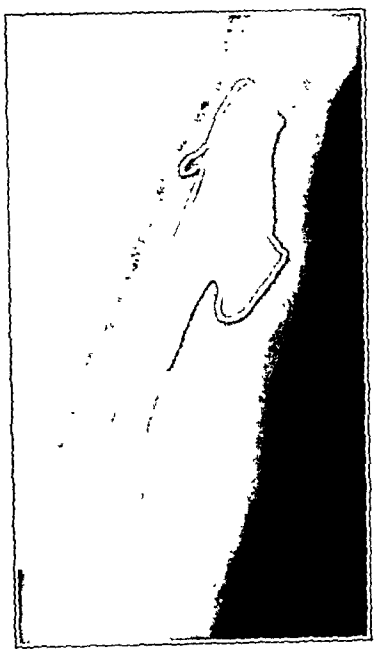

Fig. 4 (case 7).—Lateral view of left forearm, showing large exostosis of left radius.

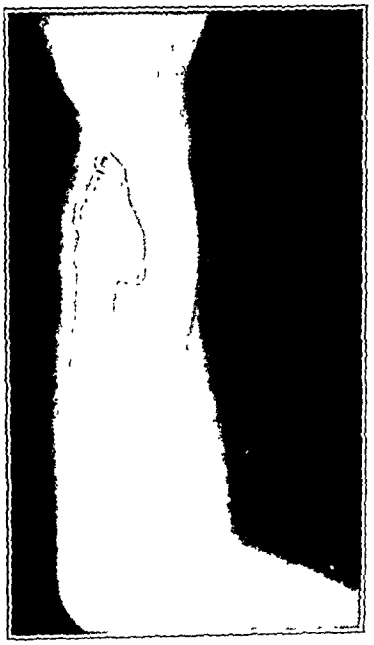

Fig. 5 (case 8).—Anteroposterior view of left forearm showing characteristic "arrow-head" deformity of lower end of ulna, with marked bowing of radius.

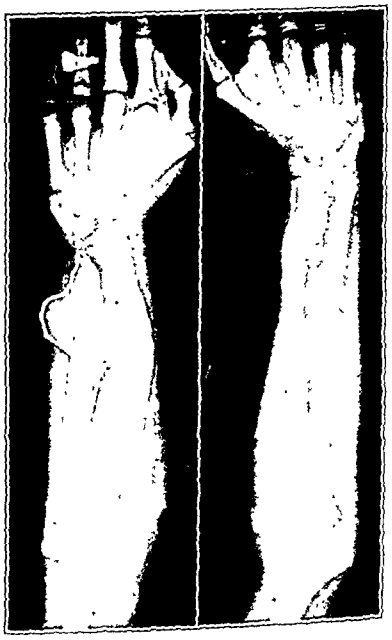

Fig. 6 (case 9).—Anteroposterior view April 7, 1931, of both forearms. Right side shows large exostosis of lower end of ulna with marked bowing of radius.

COMPLICATIONS

The commonest complications of this disease are due to pressure of the exostoses on nerves or interference with the function of muscles, tendons and joints. They are subject to trauma, since they may often project and strike against objects, particularly about the knee. Deformities, especially due to shortening of the ulna, may require correction. Five per cent are said to become malignant, but this percentage is probably too high. These conditions should remain untreated until after bony growth has stopped if possible. Indications for removal are deformity, interference with the function of joints, muscles or tendons, and evidence of a malignant condition or an increase in size after bony growth has stopped.

My series includes fifteen cases of this disease in three generations of one family. The reports illustrate well most of the points that have been discussed. The hereditary influence is well shown and in some of the

At the present time roentgenograms of both knees and both forearms show multiple exostoses of the lower ends of both femurs and upper ends of both tibias. The exostoses on the femurs are spikes, while those on the tibias are pedunculated. The left forearm shows a long pedunculated exostosis arising from the radius, lying between the radius and the ulna. The right forearm shows no tendency to recurrence of the spurs previously removed. A roentgenogram of the pelvis showed a small bony projection on the inner aspect of the neck of the right femur (fig. 1).

CASE 2.—A man aged 25, married, a chauffeur, has exostoses of both knees and of the right ankle, disclosed on examination. He has known about them for several years. Roentgenograms were not made. He is a brother of patient 1.

CASE 3.—A single man, aged 50, a laborer, 5 feet 4 inches (163 cm.) tall, has large, easily visible and palpable exostoses of the lower ends of both femurs and the upper ends of both tibias on the inside. The patient is in good health. He has had a perforated ulcer twice, about a year apart six or seven years ago. He has never been operated on for exostoses and has had no pain or inconvenience from them (figs. 2 and 3).

CASE 4.—A married man, aged 52, a printer, 5 feet 6 inches (168 cm.) tall, is a brother of patients 3 and 5 and father of

patients 7 and 8 (both girls) two unaffected sons and one affected son who died at the age of 9 years in 1918. At the age of about 20 the patient had an extosis removed from the right knee and at the present time he has small exostoses of the inner aspects of the heads of both tibias.

CASE 5.—A married man, aged 48, a foreman, 5 feet 7 inches (170 cm.) tall, a brother of patients 3 and 4 and the father of patients 9 and 10, has a small, well developed and unmistakable exostosis on the inner aspect of the upper end of the right tibia. His general health has always been good. He has experienced no inconvenience from exostoses. One daughter is unaffected.

CASE 6.—V. M. McL., a schoolgirl aged 13, has exostoses which were first noticed on the left arm at the age of 5 years. This has regressed so that there is at the present time only a slight irregularity over the lower end of the radius on the external aspect. There is a small easily palpable exostosis on the inner aspect of the upper end of the left tibia. The patient's mother, who is dead, was known to be affected and the mother's sister is patient 1.

CASE 7.—C. L., a schoolgirl aged 15, sister of patient 8 and daughter of patient 4, has exostoses on both knees which are troublesome; there is about 1 inch shortening of the right leg. There are also exostoses of the forearms (fig. 4).

CASE 8.—J. L., a schoolgirl aged 11, sister of patient 7, has marked deformity of the left forearm due to shortening of the ulna and bowing of the radius, similar to that of her cousin, patient 9. There is also deformity about both knees. Her general health is good (fig. 5).

CASE 9.—P. L., a girl aged 18, a student at business school, daughter of patient 5 and sister of patient 10, was first found to have exostoses on the left ankle at the age of 18 months. In April 1931 she was admitted to the Strong Memorial Hospital with a deformity of the right forearm and pain and swelling of the left ankle. Dr. W. W. Fray's report on the roentgenograms taken at that time is quoted at length because it illustrates many of the typical points in the x-ray examination (fig. 6).

The anteroposterior and lateral views of both knees showed numerous exostoses at the ends of the shafts of all the bones of this region. They were located at the upper end of the tibias and fibulas fairly close to the epiphysial lines but entirely on the diaphysial sides of these lines. Exostoses were also noted at the lower ends of the femur on the diaphysial side of the epiphysial line. In general, the larger and heavier exostoses were seen about the right knee. All these exostoses showed a broad, heavy base, and many of them were directed away from the joint. The epiphyses of this region showed no involvement of this type.

The anteroposterior and lateral views of both lower legs showed exostoses at the lower ends of both tibias, mostly on the lateral aspect of the bone. The adjacent portions of the tibias were deformed or modified by the pressure of these exostoses. The small bones of the ankle appeared normal except for a small excrescence on the plantar aspect of the left calcaneus.

The anteroposterior and lateral views of both forearms showed an extreme deformity with lateral bowing of the radius and marked stunting in length of the growth of the right ulna which resulted in an abnormally short right forearm. A large heavy exostosis was present at the lower end of the right ulna, which projected mainly on the medial aspect of the shaft, deforming the outlines of the adjacent bundles of muscle. The lower end of the diaphyses of this bone showed no distinction between cortex and medulla but appeared to be entirely replaced by the material in the exostoses. Owing to shortening of this bone the lower epiphysis of the ulna was at a considerable distance from the carpal bones of the wrist and did not appear to articulate with them. Only the lower end of the radius articulated with the carpal bones, producing a conspicuous anomaly of the right wrist, which produced a marked deformity. At the upper end of the ulna the articulation appeared atypical. The lower left radius showed a smaller exostosis projecting from the lower shaft. The ulna was not deformed and its lower epiphysis entered into articulation of the wrist.

Multiple cartilaginous exostoses of all regions were examined. A rather pronounced dystrophy of growth had occurred at the right lower forearm, owing undoubtedly to the failure of the lower epiphysial line of the ulna to carry on its normal function, resulting in a decreased length of bone. This was probably due to the fact that the exostoses in this region ran up to the epiphysial line itself.

April 29, 1931, the patient was operated on; the head of the right radius was excised to straighten the right forearm and several exostoses were removed from the lower end of the left tibia. The operative result was good in that the function of the arm was much better. The pathologic report on tissue from the tibia was "an irregular laying down of bone and cartilage with no evidence of tumor formation."

CASE 10.—J. L., a schoolboy aged 15, the brother of patient 9, was admitted to the Strong Memorial Hospital outpatient department Nov. 2, 1931, for x-ray examination. Exostoses had first been noted on the ribs as a small child and on the right knee at the age of 7.

A report on the x-ray examination of the long bones was exostoses in all regions examined.

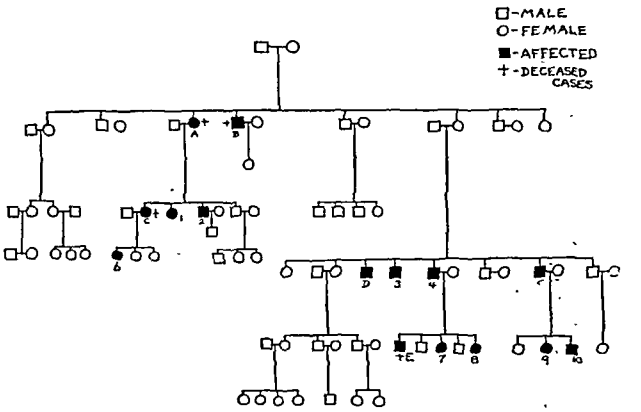

Fig. 7.—Distribution of cases in this family. Cases indicated by numerals proved by x-ray or clinical examination by author. Cases indicated by letters accepted on report of family and other physicians. The squares indicate males and the circles females; the solid black indicates affected members of the family, and the dagger indicates deceased members.

Figure 7 shows the relationship between the patients. The cases here reported are so indicated.

The patients who died or whom I have not examined but have included in the chart on testimony of the family or other physicians are indicated by letters:

CASE A.—A female patient of Dr. I. A. Cole's of Batavia had large exostoses of the knee.

CASE B.—A male patient of Dr. G. H. Knoll's of Le Roy, N. Y., had large exostoses of the ankle.

CASE C.—This woman was said by her sister and her husband to have had exostoses of the knees.

CASE D.—This man is said to have exostoses, according to his brothers; he lives at a distance and was not examined.

CASE E.—A boy aged 9 years, died in 1918 following an injury to the exostoses, operation and influenza. He was said by physicians to have had many exostoses, according to his father.

SUMMARY

1. Fifteen cases of hereditary deforming chondrodysplasia in three generations were observed. Nine of these were proved by x-ray and clinical examination by the author; the others are accepted on the strength of clinical examinations by other physicians in two cases and on the family history in the other three.

2. The ten cases reported illustrate the heredity factor. There are three brothers affected; two of them have two affected children each.

3. There are two cases of shortening and bowing of the forearm.

4. The multiplicity of exostoses is shown in all the cases. Only enough roentgenograms were taken in several of the cases to prove the diagnosis and not to show the distribution or number of exostoses. All plates have been retouched with white ink to bring out the outline of the bony growths.

41 Jackson Street.

THE MECHANISM OF FIXED DILATATION OF THE PUPIL

RESULTING FROM IPSILATERAL CEREBRAL COMPRESSION

WILLIAM LISTER REID, M.B.
AND
WILLIAM V. CONE, M.D.
MONTREAL, CANADA

For many years it has been recognized that when a patient with evidence of increased intracranial pressure becomes suddenly comatose and shows one dilated and fixed pupil, a presumptive localization of an expanding lesion in the ipsilateral cerebral hemisphere is permissible. Macewen [1] suggested the possible diagnostic value of the sign, and the more recent works of Rand,[2] Holman and Scott,[3] Kaplan [4] and Hoessly [5] have proved its practical localizing value. The mechanism producing this phenomenon has not been clear. Various explanations have been suggested, the most common being that it is due to direct pressure on the third nerve.

A series of patients admitted to the neurosurgical service with unilateral expanding cerebral lesions at some distance from the midbrain have shown ipsilateral pupillary dilatation as a sudden near terminal or terminal sign. Of these, nine patients have been selected for this report because of their conditions and one patient has been included whom Dr. F. H. Mackay allowed us to study. Six of the group died and from the anatomic studies the only explanation for the dilated and fixed pupil has seemed to be direct pressure on the third nerve by the ipsilateral hippocampal gyrus, which had herniated over the free edge of the tentorium of the cerebellum (fig. 1). In three of these fatal cases there were recent infarctions in the ipsilateral occipital lobe due, it was concluded, to disturbance of blood flow through the posterior cerebral artery or its branches by the direct pressure of the herniated brain (fig. 2). Observations made on the four patients who recovered after operative removal of the ipsilateral expanding cerebral lesion also supported the explanation of the sign arrived at from postmortem studies.

To make the evidence for concluding that the sign was due to direct pressure on the third nerve more than circumstantial, experimental extradural compression was carried out, monkeys being used for the experiments. In five of fifteen Macacus rhesus monkeys the experiments went awry as the result of technical errors. Of the remaining ten animals, seven showed ipsilateral fixed dilatation of the pupil and ptosis and three showed dilatation and slight ptosis, but some reaction to light remained. Ipsilateral hippocampal herniations (fig. 3) similar to those in human beings were produced in the ten animals by extradural compressions but no infarctions of the occipital lobes or pontile hemorrhages were encountered. The herniations produced were acute and chronic. The acute herniations were made under anesthesia, while in the chronic ones the animals were allowed to recover from the anesthesia after operation and were carefully watched as the intracranial pressure increased and the third nerve signs developed.

The histories and examinations of three patients, together with the results of one of the acute experimental herniations and one of the chronic ones, will be given in some detail, since the observations recorded are representative and show the type of studies on which our conclusions are based.

In the majority of instances in which we have observed a dilated and fixed pupil as a localizing sign, the condition of the patients has been critical and they have been unable to cooperate sufficiently for us to recognize other signs of complete paralysis of the third nerve. In the following case of extradural hemorrhage from a torn middle meningeal artery, the patient was able to carry out the examiner's instructions and there proved to be a total paralysis of the third nerve.

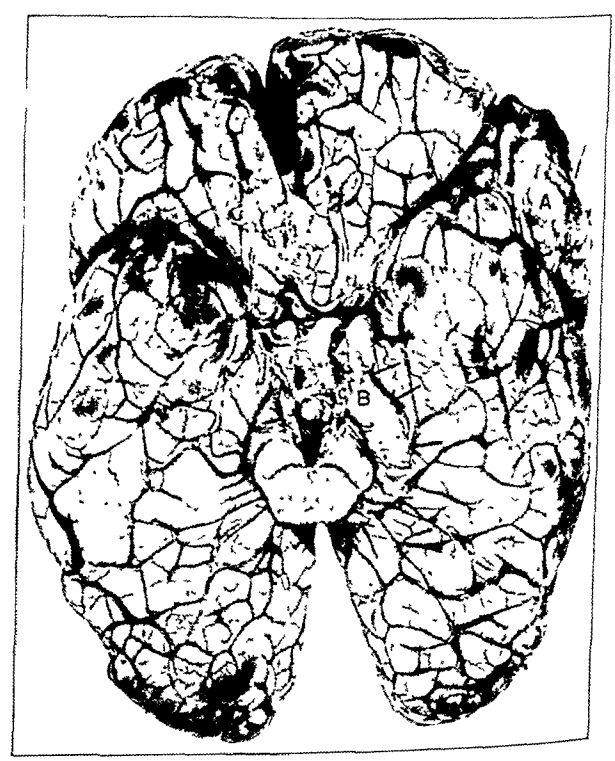

Fig. 1.—*A*, tumor in the left frontal lobe. The hippocampal gyrus on the left side shows marked herniation (*B*) directly over the third nerve (*C*). No infarction of the occipital lobe is present and there are no hemorrhages in the midbrain. Herniation outlined by arrows. This patient's left pupil was dilated and fixed at the time of admission and the left palpebral fissure was narrowed. She was clear mentally. After the history and examination were completed lumbar puncture was done. Gradually the usual headache became more intense, the blood pressure began to rise and she vomited. Stupor, coma, slowing respiration and finally cessation of breathing followed in sequence. She died fourteen hours after the lumbar puncture.

CASE 1.—G. N., a man aged 28, was referred by Dr. C. D. MacIntyre of Vankleek Hill, Ont. Twenty-four hours before admission the patient had suffered a blow to the right side of

the head and was unconscious for five or ten minutes. After he regained consciousness there was an interval of about three hours, during which time he vomited twice and complained of severe headache. He then became restless and irritable.

The attending physician noted that the right pupil was slightly larger than the left and was sluggish in its reaction to light; he made a presumptive diagnosis of hemorrhage of the middle meningeal artery. On admission to the hospital the patient cooperated with the examiner, although he was dull and resented being disturbed. By this time the right pupil was fully dilated and fixed; there was ptosis of the right upper lid and the extra-ocular muscles supplied by the third nerve were paralyzed.

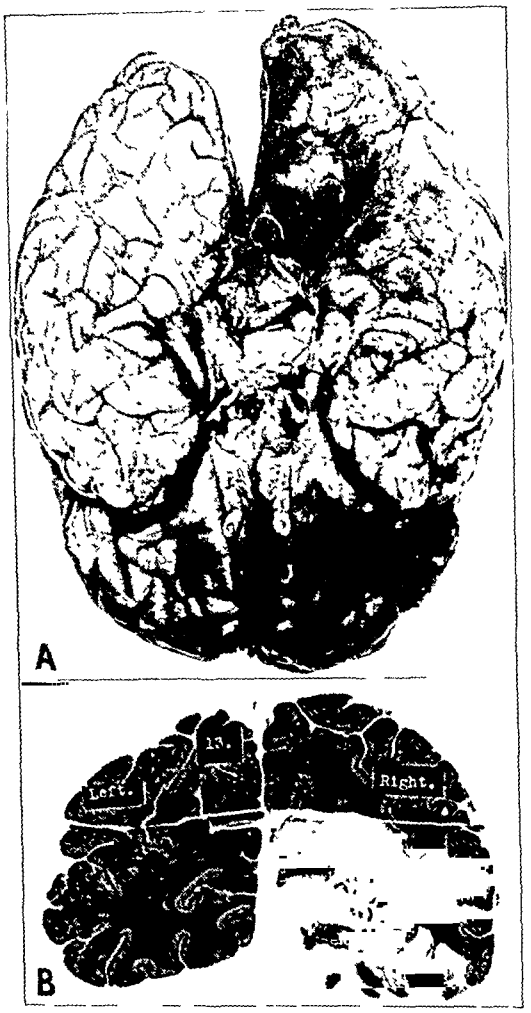

Fig. 2 (case 3).—Infarction of the mesial surface of the right occipital lobe *A* and *B*. The herniation of the hippocampal gyrus on the right side is shown in *A* at *X*. There was some herniation on the left side as well. There were no hemorrhages in the midbrain.

A right subtemporal decompression was carried out by Dr. Donald Coburn as an emergency procedure and a large extradural hematoma was removed. After operation the signs cleared rapidly. Within five hours the right pupil, although still dilated, reacted to light. The eye movements began to return and the patient complained of diplopia. He made a rapid recovery and on discharge the eye movements were normal but there remained slight ptosis and the right pupil was still slightly larger than the left, although both reacted to light and in accommodation.

The posterior cerebral artery passes lateral to and immediately above the oculomotor nerve, in close relation to the free edge of the tentorium. If the intracranial pressure is great enough to cause herniation sufficient to alter the blood flow in this artery or its branches, circulatory changes in the ipsilateral area of supply might also be expected. Infarction was found in three of the six fatal cases.

The second case, presenting late hemorrhage of the middle meningeal artery, first showed an ipsilateral dilated and fixed pupil, and then the contralateral pupil also became dilated and fixed. Although the large clot was removed and the bleeding point controlled, the patient did not recover, and both occipital lobes were found to be infarcted, the ipsilateral to a greater extent than the contralateral.

CASE 2.—E. C., a woman aged 29, referred by Dr. H. P. Macey of Frelighsburg, P. Q., with the diagnosis of hemorrhage of the middle meningeal artery, was brought to the hospital about sixteen hours after her accident. The evening preceding admission she had tripped going downstairs. She was momentarily unconscious and on recovering insisted that she felt no ill effects; after a few minutes she went to bed without assistance. The next morning she was found in deep coma, breathing irregularly, and the right pupil was dilated and fixed. She was transferred to the hospital by ambulance over a distance of 90 miles, and during the journey the left pupil also became dilated and fixed and generalized spasms, suggestive of decerebrate rigidity, occurred periodically.

An emergency operation was performed and a large extradural clot was removed from the right temporal region and the bleeding artery ligated. There was slight improvement immediately after the operation. She did not recover consciousness and died thirty-six hours later. At necropsy there was herniation of the hippocampal gyri over both free edges of the tentorium of the cerebellum. This was more marked on the right side. There were infarcted areas in both occipital lobes, also more marked in the ipsilateral hemisphere.

Hippocampal herniations causing palsy of the third nerve occur not only in head injuries but also in intracranial expanding lesions, and with these herniations the circulatory changes may occur in the areas supplied by the posterior cerebral artery. The following case resembles one described by Meyer:[6]

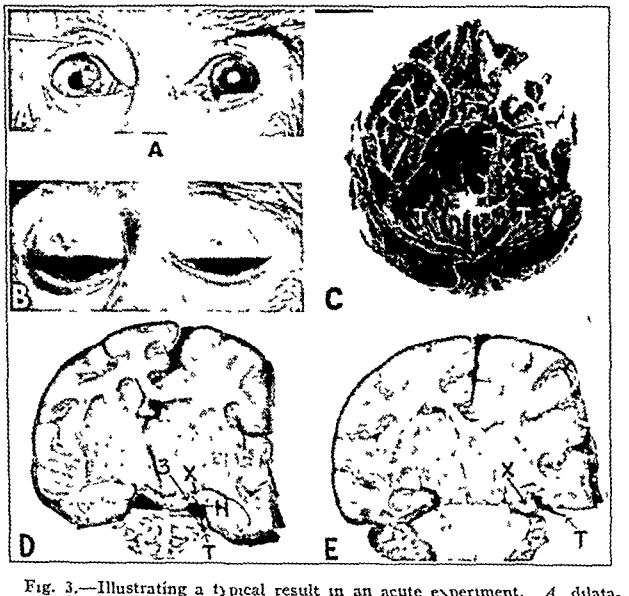

Fig. 3.—Illustrating a typical result in an acute experiment. *A*, dilatation and fixation of the left pupil and external strabismus of the left eye following ipsilateral extradural compression. *B*, later stage showing ptosis of the left upper lid. *C*, herniation of the ipsilateral hippocampal gyrus (*X*) over the free edge of the tentorium (*T*). The arrow heads outline the limits of the herniation. *D*, section showing the hippocampal gyrus (*H*) herniating over the anterior end of the free edge of the tentorium (*T*) at the point *X*, and pressing on the third nerve (*3*). *E*, section taken more posteriorly showing the herniation (*X*) forming a wedge between the free edge of the tentorium (*T*) and the midbrain.

CASE 3.—N. D., a man aged 54, was referred by Dr. Philippe Panneton of Montreal as suspected of having an intracranial tumor For two months the patient had had right frontal headache and had vomited on three or four occasions, and over this period personality changes had developed He was very uncooperative on admission to the hospital. Early bilateral papilledema was present and there was a slight weakness of the left lower part of the face and some awkwardness of the left hand. A presumptive diagnosis of a right frontal expanding lesion was made During the evening prior to the day planned for operation he was given an enema As he was expelling this he fell back unconscious, and the right pupil gradually dilated and became fixed
